#### Abstract

It has been proved that, in the classical planar circular restricted three-body problem, the degenerate saddle point processes transverse homoclinic orbits. Since the standard Smale-Birkhoff theorem cannot be directly applied to indicate the chaotic dynamics of the Smale horseshoe type, we in this note alternatively apply the Conley-Moser conditions to analytically prove the existence of a Smale horseshoe in this classical restricted three-body problem.

## 1. Introduction and Preliminaries

Few bodies problems [1-7] have been studied for long time in celestial mechanics, either as simplified models of more complex planetary systems or as benchmark models where new mathematical theories can be tested. The three-body problem has been the source of inspiration and study in celestial mechanics since Newton and Euler [8-14]. Especially, the following classical planar circular restricted three-body model has been extensively studied in the literature. Let two particles $P_{1}$ and $P_{2}$, of mass $1-\mu$ and $\mu$, move uniformly in a circular orbit about their common center of mass with angular velocity $\omega$. The orbit is located in the Oxy plane of the inertial frame of reference and the common center of mass is in the origin. The particle $P_{3}$ of infinitesimal mass $m_{3}$ moves in the gravitational field generated by $P_{1}$ and $P_{2}$. Note that since the mass of $P_{3}$ is so small, its effects on other three particles can be ignored. Without loss of generality, assume that, in the $O \overline{x y}$ plane of the rotating frame of reference, the particles $P_{1}$ and $P_{2}$ rest at the points $(\mu, 0)$ and $(\mu-1,0)$, respectively. By denoting their polar coordinates by $\rho$ and $\varphi$ and using the polar angle $\tau=\omega t$ as a new independent variable, the equation of motion of the infinitesimal particle $P_{3}$ can be written as follows:

$$
\frac{d \rho}{d \tau}=p_{\rho}
$$

$$
\begin{gather*}
\frac{d \rho_{\rho}}{d \tau}=\frac{p_{\varphi}^{2}}{\rho^{3}}-\frac{(1-\mu)(\rho-\mu \cos \varphi)}{\left(\rho^{2}+\mu^{2}-2 \rho \mu \cos \varphi\right)^{3 / 2}} \\
-\frac{\mu[\rho+(1-\mu) \cos \varphi]}{\left[\rho^{2}+(1-\mu)^{2}+2 \rho(1-\mu) \cos \varphi\right]^{3 / 2}}, \\
\left.\begin{array}{rl}
\frac{d p_{\varphi}}{d \tau}= & -\mu(1-\mu) \\
\times \rho \sin \varphi & {\left[\frac{d \varphi}{d \tau}=\frac{p_{\varphi}}{\rho^{2}}-1,\right.} \\
& -\frac{1}{\left[\rho^{2}+\mu^{2}-2 \rho \mu \cos \varphi\right]^{3 / 2}} \\
& \\
& \\
& \\
\left.\rho^{2}+(1-\mu)^{2}+2 \rho(1-\mu) \cos \varphi\right]^{3 / 2}
\end{array}\right]
\end{gather*}
$$

where $p_{\rho}$ and $p_{\varphi}$ are momenta canonically conjugate to the coordinates $\rho$ and $\varphi$, respectively.

The Hamiltonian of the system (1) is

$$
\begin{align*}
H= & \frac{1}{2}\left(p_{\rho}^{2}+\frac{p_{\varphi}^{2}}{\rho^{2}}-2 p_{\varphi}\right) \\
& -\frac{1-\mu}{\left(\rho^{2}+\mu^{2}-2 \rho \mu \cos \varphi\right)^{1 / 2}}  \tag{2}\\
& -\frac{\mu}{\left(\rho^{2}+(1-\mu)^{2}+2 \rho(1-\mu) \cos \varphi\right)^{1 / 2}} .
\end{align*}
$$

For the above classical model, Xia [4] has showed, by proper coordinate change for transforming the points at infinity to the origin (i.e, the McGehee transformation [2]), that there is a periodic solution at infinity. Moreover, from [2, 4], we know that this periodic solution is a degenerate saddle in the sense [2] that, for the Poincare map of the periodic orbit introduced at infinity, its derivative (i.e., the Jacobian) at the origin is the identity.

Further, Xia [4] and Zhu and Xiang [12] both proved the existence of transversal homoclinic orbits by the Melnikov method to the periodic solution at infinity, which corresponds to the origin under the coordinate change. However, since the origin is a degenerate fixed point, the standard Smale-Birkhoff theorem [15] cannot be directly applied to indicate the existence of a Smale horseshoe. This problem has also been pointed out by Dankowicz and Holmes [6] and Llibre and Perez-Chavela [8]. Thus, in this present note, we try to alternatively apply the Conley-Moser conditions to analytically prove the existence of a Smale horseshoe in the above classical model. For this, we introduce the ConleyMoser conditions [16] as follows.

Let $f: D \mapsto \mathbb{R}^{2}$ be an invertible map, where $D=\{(x, y) \in$ $\left.\mathbb{R}^{2} \mid 0 \leq x \leq 1,0 \leq y \leq 1\right\}$, and $f$ is at least $C^{1}$. For two given $\mu_{v}>0$ and $\mu_{h}>0$, let $K=\{1,2, \ldots, N\}(N \geq 2)$ be an index set, let $H_{1}, \ldots, H_{N}$ be the $N$ disjoint $\mu_{h}$-horizontal strips, and $V_{1}, \ldots, V_{N}$ be the $N$ disjoint $\mu_{v}$-vertical strips. For each $i, j \in$ $K$, denote $f\left(H_{i}\right) \bigcap H_{j}$ as $V_{j i}$ and $H_{i} \cap f^{-1}\left(H_{j}\right)$ as $H_{i j}$. Clearly, $H_{i j}=f^{-1}\left(V_{j i}\right)$. Define $\mathscr{H}=\bigcup_{i, j \in K} H_{i j}$ and $\mathscr{V}=\bigcup_{i, j \in K} V_{j i}$. It is also obvious that $f(\mathscr{H})=\mathscr{V}$.

For an arbitrary point $z_{0}=\left(x_{0}, y_{0}\right) \in \mathscr{H} \bigcup \mathscr{V}$, let $\left(\xi_{z_{0}}, \eta_{z_{0}}\right)$ be a vector emanating from the point $z_{0}$ in the tangent space of $z_{0}$. The stable sector at $z_{0}$ is then defined as $\mathcal{S}_{z_{0}}^{s}=\left\{\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathbb{R}^{2}| | \eta_{z_{0}}\left|\leq \mu_{h}\right| \xi_{z_{0}} \mid\right\}$. Similarly, the unstable sector at $z_{0}$ is defined as $\mathcal{S}_{z_{0}}^{u}=\left\{\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathbb{R}^{2}| | \xi_{z_{0}} \mid \leq\right.$ $\left.\mu_{v}\left|\eta_{z_{0}}\right|\right\}$. By taking the union of the stable and unstable sectors over all points in $\mathscr{H}$ and $\mathscr{V}$, we can define sector bundles as follows:

$$
\begin{array}{ll}
\mathcal{S}_{\mathscr{H}}^{s}=\bigcup_{z_{0} \in \mathscr{H}} \mathcal{S}_{z_{0}}^{s}, & \mathcal{S}_{\mathscr{V}}^{s}=\bigcup_{z_{0} \in \mathscr{V}} \mathcal{S}_{z_{0}}^{s} ; \\
\mathcal{S}_{\mathscr{H}}^{u}=\bigcup_{z_{0} \in \mathscr{H}} \mathcal{S}_{z_{0}}^{u}, & \mathcal{S}_{\mathscr{V}}^{u}=\bigcup_{z_{0} \in \mathscr{V}} \mathcal{S}_{z_{0}}^{u} . \tag{3}
\end{array}
$$

Then, the Conley-Moser conditions for the map $f$ are described by the following two assumptions.

Assumption 1. $0 \leq \mu_{\nu} \mu_{h}<1$ and, for each $i \in\{1,2, \ldots, N\}$, $f$ maps $H_{i}$ homeomorphically onto $V_{i}$; that is, $f\left(H_{i}\right)=V_{i}$. Moreover, the horizontal boundaries of $H_{i}$ are mapped to the horizontal boundaries of $V_{i}$ and the vertical boundaries of $H_{i}$ are mapped to the vertical boundaries of $V_{i}$.

Assumption 2. $D f\left(\mathcal{S}_{\mathscr{H}}^{u}\right) \subset \mathcal{S}_{\mathscr{V}}^{u}$ and $D f^{-1}\left(\mathcal{S}_{\mathscr{V}}^{s}\right) \subset \mathcal{S}_{\mathscr{H}}^{s}$. Moreover, there exists a positive number $\lambda$ satisfying $0<\lambda<$ $1-\mu_{\nu} \mu_{h}$ such that
(1) if $\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{z_{0}}^{u}$ and $\left(\xi_{f\left(z_{0}\right)}, \eta_{f\left(z_{0}\right)}\right) \doteq D f\left(z_{0}\right)\left(\xi_{z_{0}}\right.$, $\left.\eta_{z_{0}}\right) \in \mathcal{S}_{f\left(z_{0}\right)}^{u}$, then $\left|\eta_{f\left(z_{0}\right)}\right| \geq(1 / \lambda)\left|\eta_{z_{0}}\right|$;
(2) if $\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{z_{0}}^{\mathcal{S}}$ and $\left(\xi_{f^{-1}\left(z_{0}\right)}, \eta_{f^{-1}\left(z_{0}\right)}\right) \doteq D f^{-1}\left(z_{0}\right)$ $\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{f^{-1}\left(z_{0}\right)}^{S}$, then $\left|\xi_{f^{-1}\left(z_{0}\right)}\right| \geq(1 / \lambda)\left|\xi_{z_{0}}\right|$.

Based on Assumptions 1 and 2, we directly have the following.

Lemma 3 (see [16]). If the map $f$ satisfies Assumptions 1 and 2, then $f$ has an invariant Cantor set, on which it is topologically conjugate to a full shift on $N$ symbols and has
(i) a countable infinity of periodic orbits of arbitrarily high period;
(ii) an uncountable infinity of nonperiodic orbits;
(iii) a dense orbit.

Remark 4 (see [16-18]). If $f$ satisfies Assumption 2, we call that $f$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition.

## 2. Main Result

In this section, we will analytically prove the existence of a Smale horseshoe in the classical planar circular restricted three-body problem introduced in Section 1, arriving at the following theorem.

Theorem 5. For the classical planar circular restricted threebody problem introduced in Section 1, when the mass ratio $\mu$ is sufficiently small, there exists a Smale horseshoe and thus the system (1) processes chaotic dynamics of the Smale horseshoe type.

In order to prove Theorem 5, we will construct an invertible map $f$ and then verify that this $f$ satisfies the ConleyMoser conditions.
2.1. Construction of an Invertible Map $f$. According to the McGehee transformation $\rho=1 / x^{2}, p_{\rho}=y[2]$,
the Hamiltonian of the system (1) can be reformulated as follows:

$$
\begin{align*}
H= & \frac{1}{2}\left(y^{2}+x^{4} p_{\varphi}^{2}-2 p_{\varphi}\right) \\
& -\frac{(1-\mu) x^{2}}{\left(1+x^{4} \mu^{2}-2 x^{2} \mu \cos \varphi\right)^{1 / 2}} \\
& -\frac{\mu x^{2}}{\left[1+x^{4}(1-\mu)^{2}+2 x^{2}(1-\mu) \cos \varphi\right]^{1 / 2}} \tag{4}
\end{align*}
$$

Thus, the system (1) can be reformulated as

$$
\begin{gather*}
\frac{d x}{d \tau}=-\frac{1}{2} x^{3} y \\
\frac{d y}{d \tau}=p_{\varphi}^{2} x^{6}-\frac{(1-\mu)\left(1-\mu x^{2} \cos \varphi\right) x^{4}}{\left(1+\mu^{2} x^{4}-2 \mu x^{2} \cos \varphi\right)^{3 / 2}} \\
-\frac{\mu\left[1+(1-\mu) x^{2} \cos \varphi\right] x^{4}}{\left[1+(1-\mu)^{2} x^{4}+2(1-\mu) x^{2} \cos \varphi\right]^{3 / 2}}, \\
\frac{d p_{\varphi}}{d \tau}=\mu(1-\mu) x^{4} \\
\times \sin \varphi\left[\frac{d \varphi}{d \tau}=p_{\varphi} x^{4}-1,\right. \\
{\left[1+(1-u)^{2} x^{4}+2(1-\mu) x^{2} \cos \varphi\right]^{3 / 2}} \\
\left.-\frac{1}{\left(1+\mu^{2} x^{4}-2 \mu x^{2} \cos \varphi\right)^{3 / 2}}\right] \tag{5}
\end{gather*}
$$

For the energy surface $H=h$, where $h$ is a constant, there exists a $2 \pi$-periodic solution with respect to $\varphi$; that is, $\left(x, y, p_{\varphi}\right)=(0,0,-h)$. Further, near this periodic solution, by solving the Jacobi integral for $p_{\varphi}$, we have $p_{\varphi}=-h+$ $\nu_{1}(x, y, \varphi)$, where $\nu_{1}(x, y, \varphi)$ is second order in $x$ and $y$ and $2 \pi$-periodic with respect to $\varphi$.

Thus, the system (5) can be further reformulated as

$$
\begin{gather*}
\frac{d x}{d \tau}=-\frac{1}{2} x^{3} y \\
\frac{d y}{d \tau}=-(1-2 \mu)\left(x^{4}+g_{1}(x, y, \varphi, \mu)\right)  \tag{6}\\
\frac{d \varphi}{d \tau}=-1+g_{2}(x, y, \varphi, \mu)
\end{gather*}
$$

where $g_{1}$ and $g_{2}$ are $2 \pi$-periodic with respect to $\varphi, g_{1}$ is the third order in $(x, y)$, and $g_{2}$ is fourth order in $(x, y)$.

From $[4,12]$, the origin $(0,0)$ can be regarded as a periodic orbit $\gamma_{\mu}$ with period $2 \pi$ with respect to $\varphi$ in the system (6).

Moreover, the Poincaré map of the periodic orbit $(x, y)=$ $(0,0)$ has the form

$$
\begin{align*}
P_{0}: x & \longrightarrow x+k_{1} x^{3}\left(y+r_{1}(x, y)\right)  \tag{7}\\
y & \longrightarrow y+k_{2} x^{3}\left(x+r_{2}(x, y)\right)
\end{align*}
$$

where $k_{1}=\pi, k_{2}=2 \pi(1-2 \mu)$, and $r_{1}, r_{2}$ are real analytic and contain terms of at least second order in $(x, y)$.

Using polar coordinates $(\rho, \theta)$, the Poincaré map $P_{0}$ can be reformulated as

$$
\begin{align*}
P_{0}: r \longrightarrow r & -k_{1} r^{4} \cos ^{4} \theta((4 \mu-3) \sin \theta+o(r)) \\
\theta \longrightarrow \theta & -k_{2} r^{3} \cos ^{3} \theta  \tag{8}\\
& \times\left(\frac{1}{2(1-2 \mu)} \sin ^{2} \theta-\cos ^{2} \theta+o(r)\right)
\end{align*}
$$

According to formula (8), by making the following linear transformation:

$$
\begin{gather*}
x=u+v \\
y=-\sqrt{2(1-2 \mu)}(u-v) \tag{9}
\end{gather*}
$$

the system (6) can be reformulated as follows:

$$
\begin{gather*}
\frac{d u}{d \tau}=(u+v)^{3} k_{3} u \\
\frac{d v}{d \tau}=-(u+v)^{3}\left(k_{3} v+h_{1}(u, v, \varphi, \mu)\right)  \tag{10}\\
\frac{d \varphi}{d \tau}=-1+h_{2}(u, v, \varphi, \mu)
\end{gather*}
$$

where $k_{3}=\sqrt{2(1-2 \mu)} / 2$. Due to the symmetry of the problem, we subsequently restrict our discussion to the positive quadrant.

We neglect the higher order terms of (10) and then obtain that $d u / d v=-u / v$. It is clear that its solution remains on the hyperbolae $u v=c_{0}>0$, where $c_{0}$ is a constant. We substitute $v=c_{0} / u$ into the first expression of (10) and neglect the higher order terms, arriving at $d u / d \varphi=-k_{3}\left(\left(u^{2}+c_{0}\right)^{3} / u^{2}\right)$.

Let $\Sigma$ be a plane transversal to the periodic orbit $\gamma_{\mu}$ at the origin $(0,0)$ and let $U_{0}$ be a sufficiently small neighborhood of the origin $(0,0)$ in the plane $\Sigma$. For an arbitrary but fixed point $\left(u_{0}, v_{0}\right) \in U_{0} \backslash\{(0,0)\}$, we define $T_{\varphi}\left(u_{0}, v_{0}\right)=\left(u_{\varphi}, v_{\varphi}\right)$ with $T_{0}\left(u_{0}, v_{0}\right)=\left(u_{0}, v_{0}\right)$.

Assume that $u_{\varphi}=\sqrt{c_{0}} \tan \left(\phi_{\varphi} / 4\right)$; then $v_{\varphi}=$ $\sqrt{c_{0}} \cot \left(\phi_{\varphi} / 4\right)$, where $\phi_{\varphi}$ is an auxiliary variable. Substituting $u_{\varphi}=\sqrt{c_{0}} \tan \left(\phi_{\varphi} / 4\right)$ into $d u / d \varphi=-k_{3}\left(\left(u^{2}+c_{0}\right)^{3} / u^{2}\right)$, we can obtain

$$
\begin{equation*}
\phi_{\varphi}-\sin \phi_{\varphi}=k_{0}-32 k c_{0}^{3 / 2} \varphi, \quad k_{0}=\phi_{0}-\sin \phi_{0} \tag{11}
\end{equation*}
$$

where $c_{0}=u_{0} v_{0}$ and $\phi_{0}=4 \arctan \sqrt{u_{0} / v_{0}}$.

Moreover, we can calculate

$$
\begin{align*}
D T_{\varphi} & =\left[\begin{array}{ll}
\frac{\partial u_{\varphi}}{\partial u_{0}} & \frac{\partial u_{\varphi}}{\partial v_{0}} \\
\frac{\partial v_{\varphi}}{\partial u_{0}} & \frac{\partial v_{\varphi}}{\partial v_{0}}
\end{array}\right]  \tag{12}\\
& =\left[\begin{array}{cc}
\frac{u_{\varphi}}{2 u_{0}}\left(1+\Delta-3 k_{3}\left(u_{\varphi}+v_{\varphi}\right)^{3} \varphi\right) & \frac{u_{0} u_{\varphi}}{2 c}\left(1-\Delta-3 k_{3}\left(u_{\varphi}+v_{\varphi}\right)^{3} \varphi\right) \\
\frac{c}{2 u_{0} u_{\varphi}}\left(1-\Delta+3 k_{3}\left(u_{\varphi}+v_{\varphi}\right)^{3} \varphi\right) & \frac{u_{0}}{2 u_{\varphi}}\left(1+\Delta+3 k_{3}\left(u_{\varphi}+v_{\varphi}\right)^{3} \varphi\right)
\end{array}\right],
\end{align*}
$$

where $\Delta=\left(\left(u_{\varphi}+v_{\varphi}\right) /\left(u_{0}+v_{0}\right)\right)^{3}$. Clearly, $\operatorname{det} D T_{\varphi}=\Delta \neq 0$.
For the approximate system obtained by neglecting the higher order terms in the system (10), we can describe the Poincaré map $P$ defined over the plane $\Sigma$ by using the truncated flow near the degenerate saddle as follows:

$$
\begin{equation*}
P:\left(u_{0}, v_{0}\right) \longmapsto\left(u_{2 \pi}, v_{2 \pi}\right), \quad \text { where }\left(u_{0}, v_{0}\right) \in U_{0} \tag{13}
\end{equation*}
$$

Since the terms neglected in (10) are both $o\left(u^{4}, v^{4}\right)$ and $O(\mu)$, we can use this Poincaré map $P$ to approximate $P_{0}$.

Letting $u_{0}=\sqrt{c_{0}} \tan \left(\phi_{0} / 4\right)$ and $v_{0}=\sqrt{c_{0}} \cot \left(\phi_{0} / 4\right)$, then we can obtain

$$
\begin{equation*}
P^{k}\left(u_{0}, v_{0}\right) \circ\left(u_{k}, v_{k}\right)=\left(\sqrt{c_{0}} \tan \frac{\phi_{2 k \pi}}{4}, \sqrt{c_{0}} \cot \frac{\phi_{2 k \pi}}{4}\right) . \tag{14}
\end{equation*}
$$

For the system (10), the coordinate axis $v=0$ corresponds to the local stable manifold $W_{\text {loc }}^{s}\left(\gamma_{\mu}\right)$ and $u=0$ corresponds to the unstable manifold $W_{\text {loc }}^{u}\left(\gamma_{\mu}\right)$, respectively. Moreover, from [4, 12], when the mass ratio $\mu$ is sufficiently small, there exists a transversal homoclinic orbit, denoted as $\gamma$, of the periodic orbit $\gamma_{\mu}$. Thus, there exist two points $p$ and $q$ such that $p \in$ $W_{\text {loc }}^{s}\left(\gamma_{\mu}\right), q \in W_{\text {loc }}^{u}\left(\gamma_{\mu}\right)$, and $p, q \in \Sigma \bigcap \gamma$. For convenience, by introducing a scale transformation, we can further assume that $p=(1,0)$ and $q=(0,1)$.

We define $B=\left\{(u, v)| | u-1\left|\leq \delta_{1},|v| \leq \delta_{2}\right\}\right.$ and $\widetilde{B}=\left\{(u, v)| | u\left|\leq \delta_{2},|v-1| \leq \delta_{1}\right\}\right.$ as the corresponding neighborhoods of $p$ and $q$, respectively. For sufficiently small positive numbers $\delta_{1}$ and $\delta_{2}, B$ and $\widetilde{B}$ satisfy $P B \bigcap B=\emptyset$, $P^{-1} \widetilde{B} \bigcap \widetilde{B}=\emptyset$. Let $D_{k}=P^{-k} \widetilde{B} \bigcap B$. When $k$ is sufficiently large, $D_{k} \neq \emptyset$. Moreover, we also can obtain $D_{k} \bigcap D_{m}=\emptyset$ for $k \neq m$. Again let $\widetilde{D}_{k}=P^{k} D_{k}$. When $k$ is sufficiently large, $\widetilde{D}_{k} \neq \emptyset$. The relation between $D_{k}$ and $\widetilde{D}_{k}$ can be seen from Figure 1.

Since $p, q \in \Sigma \bigcap \gamma$, when $\delta_{1}$ and $\delta_{2}$ are sufficiently small, every positive half-orbit of the system (10) that starts from $\widetilde{B}$ intersects a neighborhood $U_{p}$ of the point $p$ at a point, where $U_{p} \subset \Sigma$. This can be depicted by the map $F: \widetilde{B} \rightarrow U_{p}$. It is clear that $F$ is a $C^{1}$ diffeomorphism. Let $F(u, v)=\left(F_{U}, F_{V}\right)$. Since the stable manifold and the unstable manifold of the periodic orbit $\gamma_{\mu}$ transversally intersect along $\gamma$, we can obtain $\left.\left(\partial F_{V} / \partial v\right)\right|_{q} \neq 0$.

Let $B_{h}=B \bigcap\{v=0\}, \widetilde{B}_{v}=\widetilde{B} \bigcap\{u=0\}, \partial B_{h}=\{u=$ $\left.1 \pm \delta_{1}, v=0\right\}$, and $\partial \widetilde{B}_{v}=\left\{u=0, v=1 \pm \delta_{1}\right\}$. Then,
there exists a sufficiently small $\delta_{1}$ such that $F \widetilde{B}_{v} \cap B_{h}=\{p\}$, $\left.\left(\partial F_{V} / \partial v\right)\right|_{\widetilde{B}_{v}} \neq 0, F \widetilde{B}_{v} \cap \partial B_{h}=\emptyset, F \partial \widetilde{B}_{v} \cap B_{h}=\emptyset$. Moreover, let $\partial_{v} B=\left\{(u, v) \in B \mid u=1 \pm \delta_{1}\right\}$ and $\partial_{h} \widetilde{B}=\{(u, v) \in$ $\left.\widetilde{B} \mid v=1 \pm \delta_{1}\right\}$. We can further obtain that there exists a sufficiently small $\delta_{2}$ such that $\left.\left(\partial F_{V} / \partial v\right)\right|_{\widetilde{B}} \neq 0, F \widetilde{B} \bigcap \partial_{v} B=\emptyset$, $F\left(\partial_{h} \widetilde{B}\right) \cap B=\emptyset$.

Based on $P$ and $F$, we construct a successor map $\Delta_{k}=$ $F \circ P^{k}: D_{k} \rightarrow U_{p}$. Further, we define another map $f$ over the set $\bigcup_{k} D_{k}$ such that $\left.f\right|_{D_{k}}=\Delta_{k}$. Clearly, $f$ is also a homeomorphism.
2.2. Proofs of Some Propositions for $f$. In order to prove that $f$ satisfies the Conley-Moser conditions, we need to introduce one lemma and then prove four propositions in this subsection.

Lemma 6 (see [17, 18]). Consider two invertible linear operators of $R^{1} \times R^{1}$ into itself:

$$
I=\left[\begin{array}{ll}
a & b  \tag{15}\\
c & d
\end{array}\right], \quad J=\left[\begin{array}{cc}
\Lambda & E \\
G & M
\end{array}\right]
$$

where $d M \neq 0$. Let $L>0$ be a constant such that the following conditions hold:

$$
\begin{gather*}
\|I\|<L, \quad\left\|I^{-1}\right\|<L \\
\left|d^{-1}\right|<L  \tag{16}\\
\left|E M^{-1}\right|<L
\end{gather*}
$$

Then, for arbitrary $0<\mu_{h}<\mu_{v}^{-1} \ll 1$, there exists a positive constant $\delta_{0}$, which is dependent on $L, \mu_{h}$ and $\mu_{v}$, such that if the following conditions hold:

$$
\begin{gather*}
\left|M^{-1}\right|<\delta_{0} \\
\left|\Lambda-E M^{-1} G\right|<\delta_{0} \\
\left|\Lambda M^{-1}\right|<\delta_{0}  \tag{17}\\
\left|G M^{-1}\right|<\delta_{0} \\
\left|c E M^{-1}\right|<\delta_{0}
\end{gather*}
$$

the linear map $A=I J$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition.

Figure 1: The relation between $D_{k}$ and $\widetilde{D}_{k}$.

By Lemma 6, we have the following proposition.
Proposition 7. For two arbitrary constants $\mu_{h}$ and $\mu_{v}$ with $0<$ $\mu_{h}<\mu_{v}^{-1} \ll 1$, when $k$ is sufficiently large, $\left.f\right|_{D_{k}}$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition.

Proof. Based on the chain rule on the derivative of a composite function, we can obtain

$$
\begin{align*}
\left.D f\right|_{D_{k}} & =D F \cdot D P^{k}=D F \cdot D T_{\varphi} \\
& =\left[\begin{array}{ll}
\frac{\partial F_{U}}{\partial u} & \frac{\partial F_{U}}{\partial v} \\
\frac{\partial F_{V}}{\partial u} & \frac{\partial F_{V}}{\partial v}
\end{array}\right] \cdot\left[\begin{array}{ll}
\frac{\partial u_{\varphi}}{\partial u_{0}} & \frac{\partial u_{\varphi}}{\partial v_{0}} \\
\frac{\partial v_{\varphi}}{\partial u_{0}} & \frac{\partial v_{\varphi}}{\partial v_{0}}
\end{array}\right], \tag{18}
\end{align*}
$$

where $\varphi=2 k \pi$. Let $L=\sup _{\beta \in \tilde{B}}\left\{\|D F(\beta)\|,\left\|D F(\beta)^{-1}\right\|\right.$, $\left.\left|\partial F_{V} / \partial v\right|^{-1}\right\}$. Since $\partial F_{V} /\left.\partial v\right|_{\widetilde{B}} \neq 0$ and $F$ is $C^{1}$, we have $L<+\infty$. Let $u_{0}=\delta \approx 1$ and $v_{0}=c_{0} / \delta \ll 1$. Then $\left(u_{k}, v_{k}\right) \approx\left(c_{0} / \delta, \delta\right)$.

Let $E=\partial u_{\varphi} / \partial v_{0}, \Lambda=\partial u_{\varphi} / \partial u_{0}, G=\partial v_{\varphi} / \partial u_{0}, M=$ $\partial v_{\varphi} / \partial v_{0}$. Similar to the proof of Condition 1 in [19], after some simple calculations, we can obtain that $\lim _{k \rightarrow+\infty}\left|E M^{-1}\right| \approx$ $c_{0} / \delta^{2}, \lim _{k \rightarrow+\infty}\left|M^{-1}\right|=0, \lim _{k \rightarrow+\infty}\left|\Lambda-E M^{-1} G\right|=0$, $\lim _{k \rightarrow+\infty}\left|\Lambda M^{-1}\right| \approx c_{0} / \delta^{4}, \lim _{k \rightarrow+\infty}\left|G M^{-1}\right| \approx c_{0} / \delta^{2}$, and $\lim _{k \rightarrow+\infty}\left|E M^{-1}\right| \approx c_{0} / \delta^{2}$. Further, when $c_{0} \rightarrow 0$, we can obtain that $c_{0} / \delta^{2} \rightarrow 0, c_{0} / \delta^{4} \rightarrow 0$ and $\left(\partial F_{V} / \partial u\right)\left(c_{0} / \delta^{2}\right) \rightarrow$ 0 .

Thus, there exists a $\delta>0$ such that, for sufficiently large $k$, inequalities (16) and (17) in Lemma 6 hold. Thus, according to Lemma 6, we obtain that when $k$ is large enough, $\left.f\right|_{D_{k}}$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition.

Proposition 8. When $k$ is sufficiently large, $P^{k}$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition.

Proof. Let $N \geq 2$ be an arbitrary but fixed integer. For sufficiently large $k$, let $H_{l}=D_{l+k-1}, V_{l}=f\left(D_{l+k-1}\right), V_{j i}=$ $P^{k} H_{i} \cap H_{j}$, and $H_{i j}=H_{i} \cap P^{-k} H_{j}$, where $1 \leq l, i, j \leq N$. Moreover, let $\mathscr{H}=\bigcup_{i, j} H_{i j}$ and $\mathscr{V}=\bigcup_{i, j} V_{i j}$.

For an arbitrary point $z_{0} \in \mathscr{H} \bigcup \mathscr{V}$, let $\left(\xi_{z_{0}}, \eta_{z_{0}}\right)$ be a vector emanating from the point $z_{0}$ in the tangent space of $z_{0}$. In addition, for given $\mu_{h}$ and $\mu_{v}$, let $\mathcal{S}_{z_{0}}^{u}=\left\{\left(\xi_{z_{0}}, \eta_{z_{0}}\right)| | \xi_{z_{0}} \mid<\right.$ $\left.\mu_{v}\left|\eta_{z_{0}}\right|\right\}$ be the unstable sector at $z_{0}$ and let $\mathcal{S}_{z_{0}}^{\mathcal{S}}=\left\{\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \mid\right.$ $\left.\left|\eta_{z_{0}}\right|<\mu_{h}\left|\xi_{z_{0}}\right|\right\}$ be the stable sector at $z_{0}$. Similar to Section 1, we also have $\mathcal{S}_{\mathscr{H}}^{u}, \mathcal{S}_{\mathscr{V}}^{u}, \mathcal{S}_{\mathscr{H}}^{s}$, and $\mathcal{S}_{\mathscr{V}}^{s}$.

In order to prove that $P^{k}$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition, by Remark 4, we need to prove that $P^{k}$ satisfies Assumption 2. That is, we need to prove the following:
(1) $D P^{k}\left(\mathcal{S}_{\mathscr{H}}^{u}\right) \subset \mathcal{S}_{\mathscr{V}}^{u}$ and $D P^{-k}\left(\mathcal{S}_{\mathscr{V}}^{s}\right) \subset \mathcal{S}_{\mathscr{H}}^{s} ;$
(2) there exists a constant $\lambda$ satisfying $0<\lambda<1-\mu_{h} \mu_{v}$ such that $\left|\eta_{P^{k}\left(z_{0}\right)}\right| \geq \lambda^{-1}\left|\eta_{z_{0}}\right|$ if $\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{z_{0}}^{u}$ and $\left(\xi_{P^{k}\left(z_{0}\right)}, \eta_{P^{k}\left(z_{0}\right)}\right) \doteq D P^{k}\left(z_{0}\right)\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{P^{k}\left(z_{0}\right)}^{u}$, where $\left(\xi_{P^{k}\left(z_{0}\right)}, \eta_{P^{k}\left(z_{0}\right)}\right)$ is a vector emanating from the point $P^{k}\left(z_{0}\right)$ in the tangent space of $P^{k}\left(z_{0}\right) ;\left|\xi_{P^{-k}\left(z_{0}\right)}\right| \geq$ $\lambda^{-1}\left|\xi_{z_{0}}\right|$ if $\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{z_{0}}^{s}$ and $\left(\xi_{P^{-k}\left(z_{0}\right)}, \eta_{P^{-k}\left(z_{0}\right)}\right) \dot{=}$ $D P^{-k}\left(z_{0}\right)\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{P^{-k}\left(z_{0}\right)}^{s}$, where $\left(\xi_{P^{-k}\left(z_{0}\right)}, \eta_{P^{-k}\left(z_{0}\right)}\right)$ is a vector emanating from the point $P^{-k}\left(z_{0}\right)$ in the tangent space of $P^{-k}\left(z_{0}\right)$.

First, we want to prove that $D P^{k}\left(\mathcal{S}_{\mathscr{H}}^{u}\right) \subset \mathcal{\delta}_{\mathscr{V}}^{u}$. For this, it is sufficient to prove that, for an arbitrary $z_{0}=\left(u_{0}, v_{0}\right) \in \mathscr{H}$ with $\left(\xi_{z_{0}}, \eta_{z_{0}}\right)=(1, \vartheta) \in \mathcal{S}_{z_{0}}^{u},\left(\xi_{P^{k}\left(z_{0}\right)}, \eta_{P^{k}\left(z_{0}\right)}\right)=D P^{k}\left(z_{0}\right)\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in$ $\mathcal{S}_{\mathscr{V}}^{u}$.

Clearly, $P^{k}\left(z_{0}\right) \in \mathscr{V}$ and $\vartheta$ is bounded. According to the definitions of $T_{\varphi}$ and $P, D P^{k}\left(z_{0}\right)\left(\xi_{z_{0}}, \eta_{z_{0}}\right)=$ $D T_{2 k \pi}\left(z_{0}\right)\left(\xi_{z_{0}}, \eta_{z_{0}}\right)=\left(\left(\partial u_{2 k \pi} / \partial u_{0}\right)+\left(\partial u_{2 k \pi} / \partial v_{0}\right) \vartheta\right.$, $\left.\left(\partial v_{2 k \pi} / \partial u_{0}\right)+\left(\partial \nu_{2 k \pi} / \partial \nu_{0}\right) \vartheta\right)$.

Since $\delta_{1}$ and $\delta_{2}$ for defining $B$ and $\widetilde{B}$ are chosen to be sufficiently small, $u_{0} \approx 1$ and $v_{0} \leq \delta_{2} \ll 1$. Letting $u_{0}=\delta$ and $c=u_{0} v_{0}$, then $\left(u_{2 k \pi}, v_{2 k \pi}\right) \approx(c / \delta, \delta)$. According to $D T_{\varphi}$ in Section 2.1, when $k$ is sufficiently large, we have

$$
\begin{aligned}
& \left|\frac{\left(\partial v_{2 k \pi} / \partial u_{0}\right)+\left(\partial v_{2 k \pi} / \partial v_{0}\right) \vartheta}{\left(\partial u_{2 k \pi} / \partial u_{0}\right)+\left(\partial u_{2 k \pi} / \partial v_{0}\right) \vartheta}\right| \\
& =\frac{c}{u_{2 k \pi}^{2}} \\
& \quad \times \mid\left(\Delta\left(u_{0} \vartheta-v_{0}\right)+\left(1+6 k_{3}\left(u_{2 k \pi}+v_{2 k \pi}\right)^{3} k \pi\right)\right. \\
& \left.\quad \times\left(v_{0}+u_{0} \vartheta\right)\right) \\
& \quad \times\left(\Delta\left(u_{0} \vartheta-v_{0}\right)-\left(1-6 k_{3}\left(u_{2 k \pi}+v_{2 k \pi}\right)^{3} k \pi\right)\right. \\
& \left.\quad \times\left(v_{0}+u_{0} \vartheta\right)\right)^{-1} \mid
\end{aligned}
$$

$$
\begin{align*}
& \begin{array}{l}
\approx \frac{\delta^{2}}{c} \left\lvert\,\left(\Delta\left(\delta \vartheta-\frac{c}{\delta}\right)+\left(1+6 k_{3}\left(\frac{\delta^{2}+c}{\delta}\right)^{3} k \pi\right)\right.\right. \\
\\
\left.\times\left(\delta \vartheta+\frac{c}{\delta}\right)\right) \\
\times\left(\Delta\left(\delta \vartheta-\frac{c}{\delta}\right)-\left(1-6 k_{3}\left(\frac{\delta^{2}+c}{\delta}\right)^{3} k \pi\right)\right. \\
\left.\quad \times\left(\delta \vartheta+\frac{c}{\delta}\right)\right)^{-1} \mid \\
\approx \frac{\delta^{2}}{c}\left|1+\frac{1}{3 k_{3} \delta^{3} k \pi}\right| .
\end{array} .
\end{align*}
$$

Clearly, $\lim _{k \rightarrow+\infty}\left(\delta^{2} / c\right)\left|1+1 / 3 k_{3} \delta^{3} k \pi\right|=\delta^{2} / c$. Moreover, when $c \rightarrow 0, \delta^{2} / c \rightarrow+\infty$. So, for sufficiently large $k$ and sufficiently small $\delta_{1}$ and $\delta_{2}, \mid\left(\left(\partial v_{2 k \pi} / \partial u_{0}\right)+\right.$ $\left.\left(\partial v_{2 k \pi} / \partial v_{0}\right) 9\right) /\left(\left(\partial u_{2 k \pi} / \partial u_{0}\right)+\left(\partial u_{2 k \pi} / \partial v_{0}\right) \vartheta\right) \mid>1 / \mu_{v}$. Thus, $D P^{k}\left(z_{0}\right)\left(\xi_{z_{0}}, \eta_{z_{0}}\right) \in \mathcal{S}_{\mathscr{V}}^{u}$. This directly implies that $D P^{k}\left(\mathcal{S}_{\mathscr{H}}^{u}\right) \subset \mathcal{S}_{\mathscr{V}}^{u}$.

Second, following the proof of $D P^{k}\left(\mathcal{\delta}_{\mathscr{G}}^{u}\right) \subset \mathcal{S}_{\mathscr{V}}^{u}$, we want to prove that there exists a constant $\lambda$ satisfying $0<\lambda<1-$ $\mu_{h} \mu_{v}$ such that $\left|\eta_{P^{k}\left(z_{0}\right)}\right| \geq \lambda^{-1}\left|\eta_{z_{0}}\right|$.

Similarly, for the above $\left(u_{0}, v_{0}\right)$ and $\left(u_{2 k \pi}, v_{2 k \pi}\right)$, when $k$ is sufficiently large,

$$
\begin{align*}
& \left.\left.\left\lvert\, \begin{array}{l}
\left|\frac{\partial v_{2 k \pi}}{\partial u_{0}}+\frac{\partial v_{2 k \pi}}{\partial v_{0}} \vartheta\right| \\
\left.=\frac{1}{2 u_{2 k \pi}} \right\rvert\, \Delta\left(u_{0} \vartheta-v_{0}\right)+\left(1+6 k_{3}\left(u_{2 k \pi}+v_{2 k \pi}\right)^{3} k \pi\right) \\
\\
\times\left(v_{0}+u_{0} \vartheta\right) \mid \\
\begin{array}{rl}
\left.\approx \frac{1}{2 c} \right\rvert\, \Delta\left(\delta^{2} \vartheta-c\right)
\end{array} \\
\quad+\left(1+6 k_{3}\left(\frac{\delta^{2}+c}{\delta}\right)^{3} k \pi\right) \\
\quad \times\left(c+\delta^{2}\right) \mid \\
\left.\approx \frac{\delta^{2}}{c} \right\rvert\,(1
\end{array}\right.\right)+3 k_{3} \delta^{3} k \pi\right) \vartheta \mid .
\end{align*}
$$

For given $B$ and $\widetilde{B}, \lim _{k \rightarrow+\infty}\left(\delta^{2} / c\right)\left|1+3 k_{3} \delta^{3} k \pi\right|=\infty$. So, for any constant $\lambda$ satisfying $0<\lambda<1-\mu_{h} \mu_{v}$, when $k$ is sufficiently large, $\left(\delta^{2} / c\right)\left|1+3 k_{3} \delta^{3} k \pi\right|>\lambda^{-1}$. Thus, we have $\left|\left(\partial v_{2 k \pi} / \partial u_{0}\right)+\left(\partial v_{2 k \pi} / \partial v_{0}\right) \vartheta\right|>\lambda^{-1}|\vartheta|$, implying that $\left|\eta_{P^{k}\left(z_{0}\right)}\right| \geq$ $\lambda^{-1}\left|\eta_{z_{0}}\right|$.

Third, we want to prove $D P^{-k}\left(\mathcal{S}_{\mathscr{V}}^{s}\right) \subset \mathcal{S}_{\mathscr{H}}^{\mathcal{S}}$ and $\left|\xi_{P^{-k}\left(z_{0}\right)}\right| \geq$ $\lambda^{-1}\left|\xi_{z_{0}}\right|$. For this, let $T_{\varphi}^{-1}\left(u_{\varphi}, v_{\varphi}\right)=\left(u_{0}, v_{0}\right)$ be the inverse map of $T_{\varphi}$. Then,

$$
\begin{align*}
D T_{\varphi}^{-1} & =\left(D T_{\varphi}\right)^{-1}=\left[\begin{array}{ll}
\frac{\partial u_{\varphi}}{\partial u_{0}} & \frac{\partial u_{\varphi}}{\partial v_{0}} \\
\frac{\partial v_{\varphi}}{\partial u_{0}} & \frac{\partial v_{\varphi}}{\partial v_{0}}
\end{array}\right]^{-1} \\
& =\frac{1}{\triangle}\left[\begin{array}{cc}
\frac{\partial v_{\varphi}}{\partial v_{0}} & -\frac{\partial u_{\varphi}}{\partial v_{0}} \\
-\frac{\partial v_{\varphi}}{\partial u_{0}} & \frac{\partial u_{\varphi}}{\partial u_{0}}
\end{array}\right] \tag{21}
\end{align*}
$$

For any $z_{0}=\left(u_{0}, v_{0}\right) \in \mathscr{V}$ with $\left(\xi_{z_{0}}, \eta_{z_{0}}\right)=(\omega, 1) \in \mathcal{S}_{z_{0}}^{s}$, $\left(\xi_{P^{-k}\left(z_{0}\right)}, \eta_{P^{-k}\left(z_{0}\right)}\right)=D P^{-k}\left(\xi_{z_{0}}, \eta_{z_{0}}\right)=D T_{2 k \pi}^{-1}\left(\xi_{z_{0}}, \eta_{z_{0}}\right)=$ $(1 / \triangle)\left(\left(\partial v_{2 k \pi} / \partial v_{0}\right) \omega-\left(\partial u_{2 k \pi} / \partial v_{0}\right), \quad\left(-\partial v_{2 k \pi} / \partial u_{0}\right) \omega+\right.$ $\left.\left(\partial u_{2 k \pi} / \partial u_{0}\right)\right)$. Similarly, we can prove that $\mid\left(\partial v_{2 k \pi} / \partial v_{0}\right) \omega$ $\left(\partial u_{2 k \pi} / \partial v_{0}\right) /\left(-\partial v_{2 k \pi} / \partial u_{0}\right) \omega+\left(\partial u_{2 k \pi} / \partial u_{0}\right) \mid>\mu_{h}$ and $\left|\left(\partial v_{2 k \pi} / \partial v_{0}\right) \omega-\left(\partial u_{2 k \pi} / \partial v_{0}\right)\right|>\lambda^{-1}|\omega|$. Thus, $D P^{-k}\left(\mathcal{S}_{\mathscr{V}}^{\mathcal{S}}\right) \subset \mathcal{S}_{\mathscr{H}}^{\mathcal{S}}$ and $\left|\xi_{P^{-k}\left(z_{0}\right)}\right| \geq \lambda^{-1}\left|\xi_{z_{0}}\right|$.

Based on all above analysis and Remark 4, we can then obtain that when $k$ is sufficiently large, $P^{k}$ satisfies the $\left(\mu_{h}, \mu_{v}\right)$-cone condition.

Based on Proposition 8, we can prove that $f$ satisfies the boundary condition.

Proposition 9. When $i$ and $j$ are sufficiently large, $f\left(\partial_{h} D_{i}\right) \cap D_{j}=\emptyset$ and $f D_{i} \cap \partial_{v} D_{j}=\emptyset$, where $\partial_{h} D_{i}$ is the horizontal boundary of $D_{i}$ and $\partial_{v} D_{j}$ is the vertical boundary of $D_{j}$.

Proof. Due to Proposition 8, when $k$ is sufficiently large, $P^{k}$ satisfies the $\left(\mu_{h}, \mu_{\nu}\right)$-cone condition. This implies that $P^{k}$ contracts in the horizontal direction and expands in the vertical direction. Moreover, $\mu_{\nu}$-vertical curves are mapped to $\mu_{v}$-vertical curves under the map $P^{k}$ and $\mu_{h}$-horizontal curves are mapped to $\mu_{h}$-horizontal curves under the map $P^{-k}$. Thus, for sufficiently large $i$ and $j, D_{j} \subset B, P^{i} D_{i} \subset \widetilde{B}, \partial_{v} D_{j} \subset \partial_{v} B$ and $P^{i}\left(\partial_{h} D_{i}\right) \subset \partial_{h} \widetilde{B}$. In addition, $f\left(\partial_{h} D_{i}\right) \bigcap D_{j}=(F \circ$ $\left.P^{i}\left(\partial_{h} D_{i}\right)\right) \bigcap D_{j}=\left(F \circ\left(P^{i}\left(\partial_{h} D_{i}\right)\right)\right) \bigcap D_{j}$. Thus, according to the expression $F\left(\partial_{h} \widetilde{B}\right) \bigcap B=\emptyset$ in Section 2.1, $f\left(\partial_{h} D_{i}\right) \cap D_{j}=$ $\emptyset$. Similarly, since $F \widetilde{B} \bigcap \partial_{v} B=\emptyset$, we can obtain that $f D_{i} \cap \partial_{v} D_{j}=\emptyset$.

Finally, we can prove that $f$ satisfies the intersection condition as follows.

Proposition 10. When $i$ and $j$ are sufficiently large, $f D_{i} \cap D_{j} \neq \emptyset$.

Proof. Let $C_{v}^{i}(u)=\{u\} \times\left(D_{i}\right)_{v}$ be the family of vertical curves in $D_{i}$, where $u \in B_{h}$ and $\left(D_{i}\right)_{v}=\left\{v \mid(u, v) \in B, P^{i}(u, v) \in\right.$ $\widetilde{B}\}$. From Proposition 8, $P^{i}$ with sufficiently large $i$ satisfies the $\left(\mu_{h}, \mu_{\nu}\right)$-cone condition. Thus, $P^{i} C_{v}^{i}(u)$ infinitely approaches
$\widetilde{B}_{v}$ when $i \rightarrow+\infty$. Similarly, letting $C_{h}^{i}(v)=B_{h} \times\{v\}$ be the family of horizontal curves in $D_{i}$, where $v \in\left(D_{i}\right)_{v}$, we can obtain that $C_{h}^{j}(v)$ infinitely approaches $B_{h}$ when $j \rightarrow+\infty$.

Since $F$ is $C^{1}, F\left(P^{i} C_{v}^{i}(u)\right)$ infinitely approaches $F\left(\widetilde{B}_{v}\right)$ when $i \rightarrow+\infty$. By the expression $F \widetilde{B}_{v} \cap B_{h}=\{p\}$ in Section 2.1, $F\left(P^{i} C_{v}^{i}(u)\right) \cap C_{h}^{j}(v) \neq \emptyset$. Thus, $f D_{i} \cap D_{j} \neq$ $\emptyset$.

Remark 11. In fact, we can prove that when $i, j \rightarrow+\infty$, $f C_{v}^{i}(u)$ and $C_{h}^{j}(v)$ intersect at a unique point near $p$.
2.3. Proof of Our Theorem 5. In order to prove our Theorem 5, similar to [19], we try to use Propositions 7, 9, and 10 to verify that $f$ satisfies Assumptions 1 and 2. Then, from Lemma 3, we can obtain that $f$ is a horseshoe map as follows.

Proof. From Proposition 7, when $k$ is sufficiently large, $\left.f\right|_{D_{k}}$ satisfies the $\left(\mu_{h}, \mu_{\nu}\right)$-cone condition. Thus, the map $f$ contracts in the horizontal direction and expands in the vertical direction. Moreover, $\mu_{\nu}$-vertical curves are mapped to $\mu_{\nu^{-}}$ vertical curves under the map $f$ and $\mu_{h}$-horizontal curves are mapped to $\mu_{h}$-horizontal curves under the map $f^{-1}$. Therefore, from Propositions 9 and 10, for sufficiently large $i$ and $j, f D_{i} \cap D_{j} \neq \emptyset$ is a $\left(\mu_{h}, \mu_{v}\right)$-curved rectangle and satisfies $\partial_{h}\left(f D_{i} \cap D_{j}\right) \subset \partial_{h} D_{j}$ and $\partial_{v}\left(f D_{i} \cap D_{j}\right) \subset \partial_{v}\left(f D_{i}\right)$. Similarly, for sufficiently large $i$ and $j, f^{-1}\left(f D_{i} \cap D_{j}\right) \neq \emptyset$ is also a $\left(\mu_{h}, \mu_{v}\right)$-curved rectangle and satisfies $\partial_{v} f^{-1}\left(f D_{i} \cap D_{j}\right) \subset$ $\partial_{v} D_{i}$ and $\partial_{h} f^{-1}\left(f D_{i} \cap D_{j}\right) \subset \partial_{h}\left(f^{-1} D_{j}\right)$.

Let $N \geq 2$ be an arbitrary but fixed positive integer. For sufficiently large $k$, $i$, and $j$, by letting $H_{l}=D_{l+k-1}$, $V_{l}=f\left(D_{l+k-1}\right), f D_{i} \cap D_{j}=V_{(j-k+1)(i-k+1)}$, and $D_{i} \cap f^{-1} D_{j}=$ $H_{(i-k+1)(j-k+1)}$, where $1 \leq l \leq N$, we can obtain that $f$ satisfies Assumption 1. In addition, due to Remark 4, $f$ obviously satisfies Assumption 2.

Thus, for an arbitrary but fixed $N \geq 2$, when $k$ is sufficiently large, the map $f$ over the set $\bigcup_{i=0}^{N-1} D_{k+i}$ satisfies Assumptions 1 and 2; that is, $f$ satisfies the Conley-Moser conditions.

By Lemma 3, when $k$ is sufficiently large, $f$ has an invariant Cantor set, on which it is topologically conjugate to a full shift on $N$ symbols. This directly implies that $f$ is a horseshoe map.

## 3. Conclusions

In this present note, we studied the existence of a Smale horseshoe in a planar circular restricted three-body problem by first defining an invertible map $f$ and then proving that this $f$ satisfies the Conley-Moser conditions. This implies that the planar circular restricted three-body problem processes chaotic dynamics of the Smale horseshoe type.
