# THE LIMITS OF SINAI'S SIMPLE RANDOM WALK IN RANDOM ENVIRONMENT 

By Yueyun Hu and Zhan Shi<br>U niversité Paris VI

We study the sample path asymptotics of a class of recurrent diffusion processes with random potentials, including examples of Sinai's simple random walk in random environment and Brox's diffusion process with Brownian potential. The main results consist of several integral criteria which completely characterize all the possible Lévy classes, therefore providing a very precise image of the almost sure asymptotic behaviors of these processes.

## 1. Introduction.

1.1. Simple random walk in random environment. Problems related to random environments arise naturally in several branches of physics (cf. [2] for an overview) and receive much attention from both mathematicians and physicists. The most elementary model is Sinai's simple random walk in random environment, which can be described as follows: let $\left\{\xi_{i}\right\}_{i \in \mathbb{N}}$ be a sequence of random variables taking values in ( 0,1 ). Define a random walk $\left\{S_{n}\right\}_{\mathrm{n} \geq 0}$ by $\mathrm{S}_{0}=0$ and

$$
\mathbb{P}\left(\mathrm{S}_{\mathrm{n}+1}=\mathrm{j} \mid \mathrm{S}_{\mathrm{n}}=\mathrm{i} ; \Xi\right)= \begin{cases}\xi_{i}, & \text { if } \mathrm{j}=\mathrm{i}+1 \\ 1-\xi_{i}, & \text { if } \mathrm{j}=\mathrm{i}-1 \\ 0, & \text { otherwise }\end{cases}
$$

for any $\mathrm{n} \geq 1$ and $\mathrm{i} \in \mathbb{N}$, where $\exists=\left\{\xi_{j}\right\}_{j \in \mathbb{N}}$ as defined is the so-called random environment. Observe that both the environment and the walk are random under $\mathbb{P}$. In physics, it is often the case that little is known about the realization of random environment. It is therefore convenient to formulate results under the absolute probability $\mathbb{P}$ (the so-called annealed setting). Throughout the paper, it is under probability $\mathbb{P}$ we shall be working, and anything like "with probability 1" or "almost surely" is to be understood with respect to $\mathbb{P}$. (In the literature, there is also much interest in the "quenched" setting, i.e., the random walk under the conditional probability $\mathbb{P}(\cdot \mid \Xi)$; cf. for example[15] and [13]).

A remarkable result in the study of random walk in random environment (RWRE) is Sinai's theorem [30], which establishes convergence in distribu-

[^0]tion, denoted by "law" in the sequel, of $S_{n} /(\log n)^{2}$ to some nondegenerate variable. The limit law was later determined in [20] and [14] independently.

Theorem A (Sinai [30], Kesten [20], Golosov [14]). Assuming that
(1.1) $\left\{\xi_{i}\right\}_{i \in \mathbb{Z}}$ areindependent and identically distributed,

$$
\begin{gather*}
\mathbb{P}\left(\nu<\xi_{0}<1-\nu\right)=1, \quad \text { for some } \nu>0  \tag{1.2}\\
\mathbb{E} \log \frac{\xi_{0}}{1-\xi_{0}}=0  \tag{1.3}\\
0<\sigma^{2}=\mathbb{E}\left(\log \frac{\xi_{0}}{1-\xi_{0}}\right)^{2}<\infty \quad \text { as defined, }
\end{gather*}
$$

we have

$$
\begin{gather*}
\frac{\sigma^{2}}{(\log n)^{2}} \mathrm{~S}_{\mathrm{n}} \xrightarrow{\operatorname{low}} \mathrm{~b}_{\infty},  \tag{1.5}\\
\frac{\sigma^{2}}{(\log n)^{2}} \max _{0 \leq k \leq n} \mathrm{~S}_{\mathrm{n}} \xrightarrow{\operatorname{law}} \overline{\mathrm{~b}}_{\infty}, \tag{1.6}
\end{gather*}
$$

where $b_{\circ}$ is a symmetric variable, and $\bar{b}_{\circ}$ is positive. Moreover, their respective laws are characterized via Laplace transforms

$$
\begin{gathered}
\mathbb{E} \exp \left(-\lambda\left|b_{\infty}\right|\right)=\frac{\cosh (\sqrt{2 \lambda})-1}{\lambda \cosh \sqrt{2 \lambda}}, \\
\mathbb{E} \exp \left(-\lambda \overline{\mathrm{b}}_{\infty}\right)=\frac{\tanh \sqrt{2 \lambda}}{\sqrt{2 \lambda}}, \quad \lambda>0 .
\end{gathered}
$$

Remark 1.1. Loosely speaking, Theorem A tells us that, for large $n$, a "typical" value of $S_{n}$ or $\max _{0 \leq k \leq n} S_{k}$ is of order $(\log n)^{2}$, which is far smaller than $\mathrm{n}^{1 / 2}$, the magnitude order of a usual simple symmetric random walk [in a nonrandom environment, i.e., $\sigma=0$ in (1.4)]. An explanation for this is that it takes a long time for $S_{n}$ to go through the deep "valleys" of the random environment $\Xi$. Simple heuristic arguments for getting the $(\log n)^{2}$ rate can be found in [30] or [26], page 276. We also mention that conditions bearing different natures in (1.1)-(1.4) are also adopted in the literature; compare, for example, [21] and [9] in the discrete-time setting and [18] and [4] in the continuous-time setting.

In contrast to the huge number of results concerning random environments, relatively little is known about the almost sure asymptotic behavior of Sinai's RWRE $S_{n}$. To the best of our knowledge, this problem was first attacked in [8].

Theorem $B$ (Deheuvels and Révész [8]). Assuming (1.1)-(1.4), for any $\varepsilon>0$ and $\mathrm{p} \geq 3$, the following inequalities hold almost surely for all but finitely many n :

$$
\begin{align*}
\frac{(\log n)^{2}}{(\log \log n)^{2+\varepsilon}} & \leq \max _{0 \leq k \leq n}\left|S_{k}\right|  \tag{1.7}\\
& \leq(\log n)^{2}\left(\log _{2} n\right)^{2} \cdots\left(\log _{p-1} n\right)^{2}\left(\log _{p} n\right)^{2+\varepsilon} \tag{1.8}
\end{align*}
$$

where $\log _{j} n$ denotes the jth iterative logarithmic function.
Remark 1.2. In the "reflecting" setting (i.e., a positive random walk with a reflecting barrier at 0 ), Theorem $B$ was recently recovered in [6], using Lyapunov functions.

Natural questions arise here: what is the exact amount of almost sure asymptotic behavior of $S_{n}$ ? Are (1.7) and/or (1.8) sharp? More generally, we suggest studying the following problems.

1. How big can $S_{n}$ (resp. $\left.\max _{0 \leq k \leq n} S_{n}, \max _{0 \leq k \leq n}\left|S_{k}\right|\right)$ be?
2. How small can $\max _{0 \leq k \leq n}\left|S_{k}\right|$ be?
3. How small can $\max _{0 \leq k \leq n} S_{k}$ be?

Observe that by symmetry, the corresponding "how small" problem for $S_{n}$ is equivalent to (1).

We provide complete solutions to problems (1)-(3), via three integral tests which characterize all the possible Lévy classes of $\left\{S_{n}\right\}_{n \geq 0}$. It is noted that $\max _{0 \leq k \leq n}\left|S_{k}\right|$ and $\max _{0 \leq k \leq n} S_{k}$ have very different lower functions. This can be understood as follows: when $\max _{0 \leq \mathrm{k} \leq \mathrm{n}} \mathrm{S}_{\mathrm{k}}$ is small, the RWRE makes some extraordinarily large negative excursions.

Before stating our main results, we give some precision about conditions of regularity. Though the "classical" conditions (1.1)-(1.4) are adopted by many mathematicians and physicists in the study of Sinai's recurrent RWRE, we assume in this paper a somewhat weaker condition (possibly in an enlarged probability space): there exists a coupling for $\Xi$ and standard "two-sided" Brownian motion $\{W(y) ; y \in \mathbb{R}\}$, such that, for all $n \geq 1$,

$$
\begin{equation*}
\mathbb{P}\left[\sup _{1 \leq|m| \leq n}\left|\sum_{j=1}^{m} \log \left(\frac{1-\xi_{j}}{\xi_{j}}\right)-\sigma W(m)\right| \geq C_{1} \log n\right] \leq \frac{C_{2}}{n^{C_{3}}}, \tag{1.9}
\end{equation*}
$$

where $\mathrm{C}_{\mathrm{i}}>0(1 \leq \mathrm{i} \leq 3)$ and $\sigma>0$ are finite constants (for negative m's, $\sum_{j=1}^{m} x_{j}=x_{-1}+\cdots+x_{m}$ ) as defined. By the well-known Komlós-MajorTusnády [24] strong approximation theorem, (1.1)-(1.4) together imply (1.9). Recall that according to [31], Theorem 1.7(iii), (1.9) also ensures the recurrence of $S_{n}$.

Theorem 1.3. Let $\left\{a_{n}\right\}_{n \geq 1}$ be a sequence of positive nondecreasing numbers. We have, under (1.9),

$$
\begin{align*}
\mathbb{P}\left[S_{n}\right. & \left.>(\log n)^{2} a_{n} \text { i.o. }\right] \\
& =\left\{\begin{array}{lll}
0 & \Leftrightarrow & \sum_{n \geq 2} \frac{a_{n}}{n \log n} \exp \left(-\frac{\pi^{2} \sigma^{2}}{8} a_{n}\right)\left\{\begin{array}{l}
<\infty \\
=\infty \\
1
\end{array}\right.
\end{array}\right. \tag{1.10}
\end{align*}
$$

where we adopt the usual symbol "i.o." denoting "infinitely often" as the relevant variable tends to infinity. In particular,

$$
\begin{equation*}
\limsup _{n \rightarrow \infty} \frac{S_{n}}{(\log n)^{2} \log \log \log n}=\frac{8}{\pi^{2} \sigma^{2}} \text { a.s. } \tag{1.11}
\end{equation*}
$$

We can replace $S_{n}$ by either $\max _{0 \leq k \leq n}\left|S_{k}\right|$ or $\max _{0 \leq k \leq n} S_{k}$ in (1.10) and (1.11).

Theorem 1.4. Let $\left\{a_{n}\right\}_{n \geq 1}$ be a sequence of positive nondecreasing numbers. Assuming (1.9),

$$
\mathbb{P}\left[\max _{0 \leq k \leq n}\left|S_{k}\right| \leq \frac{(\log n)^{2}}{a_{n}} \text { i.o. }\right]=\left\{\begin{array} { l } 
{ 0 } \\
{ 1 }
\end{array} \Leftrightarrow \sum _ { n \geq 2 } \frac { \sqrt { a _ { n } } } { n \operatorname { l o g } n } \operatorname { e x p } ( - \frac { a _ { n } } { \sigma ^ { 2 } } ) \left\{\begin{array}{c}
<\infty \\
=\infty
\end{array} .\right.\right.
$$

As a consequence, we obtain the following Chung-type iterated logarithm law:

$$
\liminf _{n \rightarrow \infty} \frac{\log \log \log n}{(\log n)^{2}} \max _{0 \leq k \leq n}\left|S_{k}\right|=\frac{1}{\sigma^{2}} \text { a.s. }
$$

THEOREM 1.5. If $\left\{a_{n}\right\}_{n \geq 1}$ is positive nondecreasing, and if (1.9) holds,

$$
\mathbb{P}\left[\max _{0 \leq k \leq n} S_{k} \leq \frac{(\log n)^{2}}{a_{n}} \text { i.o. }\right]=\left\{\begin{array} { l } 
{ 0 } \\
{ 1 }
\end{array} \Leftrightarrow \sum _ { n } \frac { 1 } { n \sqrt { a _ { n } } \operatorname { l o g } n } \left\{\begin{array}{l}
<\infty \\
=\infty
\end{array}\right.\right.
$$

Therefore, with probability 1 ,

$$
\liminf _{n \rightarrow \infty} \frac{(\log \log n)^{a}}{(\log n)^{2}} \max _{0 \leq k \leq n} S_{k}= \begin{cases}0, & \text { if } a \leq 2 \\ \infty, & \text { otherwise }\end{cases}
$$

Theorems 1.3-1.5 are proved in Section 10.
1.2. Diffusion with Brownian potential. The continuous-time analogue of Sinai's RWRE is Brox's diffusion process $\{\mathrm{X}(\mathrm{t})$; $\mathrm{t} \geq 0$, formally defined by

$$
\left\{\begin{align*}
\mathrm{dX}(\mathrm{t}) & =\mathrm{d} \beta(\mathrm{t})-\frac{1}{2} \mathrm{~W}^{\prime}(\mathrm{X}(\mathrm{t})) \mathrm{dt}  \tag{1.12}\\
\mathrm{X}(0) & =0
\end{align*}\right.
$$

where $\{\beta(\mathrm{t}) ; \mathrm{t} \geq 0\}$ and $\{\mathrm{W}(\mathrm{x}) ; \mathrm{x} \in \mathbb{R}\}$ are independent one-dimensional Brownian motions (W being "two-sided") with $\beta(0)=\mathrm{W}(0)=0$. Strictly speaking, instead of writing the formal derivative of W in (1.12), we should
consider $X$ as a diffusion process with generator

$$
\frac{1}{2} e^{w(x)} \frac{d}{d x}\left(e^{-w(x)} \frac{d}{d x}\right)
$$

The analogue of the weak convergence (1.5) for $X$ is established in Brox [3]. Again, it results from the intuitive idea that $X$ spends a long time in the "valleys" of W. The study of X usually relies on rigorous treatment of the valleys, which, originally due to Sinai and Brox, is now much developed for a large class of processes. See, for example, [32] and [25] together with their references. In Section 8, we solve the problem of determining the almost sure asymptotics of $X$. The answer is a continuous-time analogue of that to Sinai's RWRE.

Theorem 1.6. For any nondecreasing function $f>0$,

$$
\mathbb{P}\left[X(t)>(\log t)^{2} f(t) \text { i.o. }\right]=\left\{\begin{array} { l } 
{ 0 } \\
{ 1 }
\end{array} \Leftrightarrow \int ^ { \infty } \frac { f ( t ) } { t \operatorname { l o g } t } \operatorname { e x p } ( - \frac { \pi ^ { 2 } } { 8 } f ( t ) ) d t \left\{\begin{array}{c}
<\infty \\
=\infty \\
\infty
\end{array}\right.\right.
$$

In particular,

$$
\limsup _{t \rightarrow \infty} \frac{X(t)}{(\log t)^{2} \log \log \log t}=\limsup _{t \rightarrow \infty} \frac{\sup _{0 \leq s \leq t}|X(s)|}{(\log t)^{2} \log \log \log t}=\frac{8}{\pi^{2}} \quad \text { a.s. }
$$

Theorem 1.7. For any nondecreasing function $f>0$,

$$
\mathbb{P}\left[\sup _{0 \leq s \leq t}|X(s)| \leq \frac{(\log t)^{2}}{f(t)} \text { i.o. }\right]=\left\{\begin{array} { l } 
{ 0 } \\
{ 1 }
\end{array} \Leftrightarrow \int ^ { \infty } \frac { \sqrt { f ( t ) } } { t \operatorname { l o g } t } \operatorname { e x p } ( - f ( t ) ) d t \left\{\begin{array}{l}
<\infty \\
=\infty \\
=\infty
\end{array}\right.\right.
$$

In particular,

$$
\liminf _{t \rightarrow \infty} \frac{\log \log \log t}{(\log t)^{2}} \sup _{0 \leq s \leq t}|X(s)|=1 \quad \text { a.s. }
$$

Theorem 1.8. For any nondecreasing function $f>0$,

$$
\mathbb{P}\left[\sup _{0 \leq s \leq t} X(s) \leq \frac{(\log t)^{2}}{f(t)} \text { i.o. }\right]=\left\{\begin{array} { l } 
{ 0 } \\
{ 1 }
\end{array} \Leftrightarrow \int ^ { \infty } \frac { d t } { t \sqrt { f ( t ) } \operatorname { l o g } t } \left\{\begin{array}{l}
<\infty \\
=\infty
\end{array}\right.\right.
$$

The rest of the paper is organized as follows. In Section 2, a distributional result concerning one-dimensional Brownian motion is obtained, which may be of independent interest and which ultimately plays an important role, in Sections 5-8, in the proofs of our main theorems as well as in the forthcoming key estimates and technical lemmas. In Section 3, we present some key estimates (Propositions 3.1-3.3) for tail probabilities in the general setting of a diffusion process with random potential. Two lemmas are stated in Section 4, and they are proved in Sections 6 and 7, respectively. Section 5 is devoted to the proof of the key estimates. Based on the key estimates, Theorems
1.6-1.8 are proved in Section 8, where we shall actually prove a general result implying Theorems $1.6-1.8$ as special cases. In Section 9, a Skorokhod-type embedding is presented, which relates Sinai's RWRE to a Brox-type diffusion process with random potential. We prove Theorems 1.3-1.5 in Section 10. Finally, to illustrate how our approach allows dealing with other aspects of Sinai's RWRE, we study weak convergence in Section 11. In particular, the limit law of $\max _{0 \leq k \leq n} S_{k}$ stated in Theorem $A$ is recovered.
2. One-dimensional Brownian motion. In the sequel, for any stochastic process $\xi$ and $\mathrm{u} \in \mathbb{R}$, we write indifferently $\xi(\mathrm{u})$ or $\xi_{u}$, and define,

$$
\begin{align*}
\bar{\xi}(\mathrm{u}) & =\sup _{\mathrm{s} \in[0, \mathrm{u}]} \xi(\mathrm{s}) \quad \text { as defined, }  \tag{2.1}\\
\underline{\xi}(\mathrm{y}) & =\inf _{\mathrm{s} \in[0, \mathrm{u}]} \xi(\mathrm{s}) \quad \text { as defined, }  \tag{2.2}\\
\xi^{*}(\mathrm{u}) & =\sup _{\mathrm{s} \in[0, \mathrm{u}]}|\xi(\mathrm{s})| \quad \text { as defined, } \tag{2.3}
\end{align*}
$$

where, by abuse of notation, $[0, u$ ] means [ $u, 0]$ for negative $u$ 's.
Let $\{\mathrm{W}(\mathrm{t}) ; \mathrm{t} \geq 0\}$ be one-dimensional Brownian motion, starting from 0 . Define

$$
\begin{align*}
W^{\#}(t) & =\sup _{0 \leq r \leq s \leq t}(W(s)-W(r))  \tag{2.4}\\
& =\sup _{0 \leq s \leq t}(W(s)-\underline{W}(s)) \text { as defined }
\end{align*}
$$

for $t \geq 0$. Here is the main result of the section.
Theorem 2.1. Le $\bar{W}$ and $W^{\#}$ be as in (2.1) and (2.4). For $0<a \leq b$ and $\mathrm{t}>0$,

$$
\begin{align*}
& \mathbb{P}\left(\overline{\mathrm{W}}(\mathrm{t})<\mathrm{a} ; \mathrm{W}^{\#}(\mathrm{t})<\mathrm{b}\right) \\
& \quad=\frac{4}{\pi} \sum_{\mathrm{k}=0}^{\infty} \frac{1}{2 \mathrm{k}+1} \exp \left(-\frac{(2 \mathrm{k}+1)^{2} \pi^{2} \mathrm{t}}{8 \mathrm{~b}^{2}}\right) \sin \left(\left(\mathrm{k}+\frac{1}{2}\right) \frac{\pi \mathrm{a}}{\mathrm{~b}}\right) . \tag{2.5}
\end{align*}
$$

Proof. By scaling, we only have to treat the case $t=1$. For each fixed $x \in \mathbb{R}$, let

$$
H_{x}=\inf \{t>0: W(t)=x\} \quad \text { as defined. }
$$

Consider the measurable events

$$
\begin{aligned}
E_{1} & =\{\bar{W}(1)<a\} \quad \text { (as defined) } \\
& =\left\{H_{a}>1\right\}, \\
E_{2}= & \left\{W^{\#}(1)<b\right\} \quad \text { (as defined) } \\
= & \left\{\sup _{0 \leq s \leq 1}(W(s)-\underline{W}(s))<b\right\} .
\end{aligned}
$$

Recall that $\mathrm{a} \leq \mathrm{b}$. When $\omega \in \mathrm{E}_{1} \cap \mathrm{E}_{2}$, there are two possible situations, namely:
(i) either $\mathrm{a}-\mathrm{b}<\mathrm{W}(\mathrm{s})<\mathrm{a}$ for $0 \leq \mathrm{s} \leq 1$;
(ii) or W hits $\mathrm{a}-\mathrm{b}$ before hitting a and before time 1, and for $\{\alpha(\mathrm{s})=$ $\left.\mathrm{W}\left(\mathrm{s}+\mathrm{H}_{\mathrm{a}-\mathrm{b}}\right)+(\mathrm{b}-\mathrm{a}) ; \mathrm{s} \geq 0\right\}$, the process $\mathrm{s} \mapsto \alpha(\mathrm{s})-\inf _{0 \leq \mathrm{r} \leq \mathrm{s}} \alpha(\mathrm{r})$ stays below $b$ until $1-\mathrm{H}_{\mathrm{a}-\mathrm{b}}$.
Hence

$$
\begin{aligned}
\mathbb{P}\left(E_{1} \cap E_{2}\right)= & \mathbb{P}\left(H_{a-b}>1 ; H_{a}>1\right) \\
& +\mathbb{P}\left(H_{a-b}<\min \left(1, H_{a}\right) ;\right. \\
& \left.\sup _{0 \leq s \leq 1-H_{a-b}}\left(\alpha(s)-\inf _{0 \leq r \leq s} \alpha(r)\right)<b\right) \\
= & \mathbb{P}\left(\sup _{0 \leq u \leq 1} \gamma(\mathrm{u})<b\right),
\end{aligned}
$$

where the process $\{\gamma(u) ; u \geq 0\}$ is defined by

$$
\gamma(u)= \begin{cases}W(u)+(b-a), & \text { if } 0 \leq u \leq H_{a-b}, \\ \alpha\left(u-H_{a-b}\right)-\inf _{0 \leq r \leq u-H_{a-b}} \alpha(r), & \text { if } u \geq H_{a-b} .\end{cases}
$$

In words, the process $\gamma$ begins life as the shifted Brownian motion W + (ba), and when hitting 0 for the first time, it follows the path of $\mathrm{s} \mapsto \alpha(\mathrm{s})-$ $\inf _{0 \leq r \leq s} \alpha(r)$. Observe that $\alpha$ is Brownian motion starting from 0 , independent of $F_{H_{a-b}}$ ( $F$ denoting the natural filtration of $W$ ). On the other hand, it follows from Lévy's identity that $\left\{\alpha(\mathrm{s})-\inf _{0 \leq r \leq s} \alpha(r) ; \mathrm{s} \geq 0\right\}$ is reflecting Brownian motion (i.e., behaving like $|\mathrm{W}|$ ). Therefore, by the strong Markov property,

$$
\{\gamma(\mathrm{u}) ; \mathrm{u} \geq 0\} \stackrel{\text { law }}{=}\{|\mathrm{W}(\mathrm{u})+(\mathrm{b}-\mathrm{a})| ; \mathrm{u} \geq 0\} \text { by law, }
$$

where ${ }^{\text {law }} \stackrel{\text { " stands }}{ }$ for identity in distribution. Consequently,

$$
\begin{aligned}
\mathbb{P}\left(E_{1} \cap E_{2}\right) & =\mathbb{P}\left(\sup _{0 \leq u \leq 1}|W(u)+(b-a)|<b\right) \\
& =\mathbb{P}(\bar{W}(1)<a ; \underline{W}(1)>-(2 b-a))
\end{aligned}
$$

Theorem 2.1 now follows from the well-known joint distribution of $\bar{W}(1)$ and W(1) (cf. [12], page 342).

Corollary 2.2. Thejoint distribution-density function of $\left(\bar{W}, W^{\#}\right)$ is given by

$$
\frac{1}{\mathrm{db}} \mathbb{P}\left(\overline{\mathrm{~W}}(1)<\mathrm{a} ; \mathrm{W}^{\#}(1) \in \mathrm{db}\right)=\left(\frac{8}{\pi}\right)^{1 / 2} \sum_{\mathrm{k}=-\infty}^{\infty}(-1)^{\mathrm{k}} \mathrm{k} \exp \left(-\frac{(\mathrm{a}+2 \mathrm{~kb})^{2}}{2}\right)
$$

for $0<\mathrm{a}<\mathrm{b}$. Consequently, there exist universal constants $\mathrm{C}_{4}>0$ and $\mathrm{C}_{5}>0$ such that

$$
\begin{align*}
\frac{C_{4}}{b} \exp \left(-\frac{(2 b-a)^{2}}{2}\right) & \leq \mathbb{P}\left(\bar{W}(1)<a ; W^{\#}(1)>b\right) \\
& \leq \frac{C_{5}}{b} \exp \left(-\frac{(2 b-a)^{2}}{2}\right), \quad 1 \leq a<b \tag{2.6}
\end{align*}
$$

For the proof, take $t=1$ in (2.5), differentiate on both sides with respect to $b$ and use the Poisson summation formula.
3. Key estimates. Our main concern is Sinai's RWRE and Brox's diffusion process. Therefore, we develop a method which can be applied to both processes.

Consider a Brox-type diffusion process $\{\mathbb{X}(\mathrm{t}) ; \mathrm{t} \geq 0\}$ formally defined by

$$
\left\{\begin{aligned}
\mathrm{d} \mathbb{X}(\mathrm{t}) & =\mathrm{d} \beta(\mathrm{t})-\frac{1}{2} \mathbb{W}^{\prime}(\mathbb{X}(\mathrm{t})) \mathrm{dt} \\
\mathbb{X}(0) & =0,
\end{aligned}\right.
$$

where $\{\beta(\mathrm{t}) ; \mathrm{t} \geq 0\}$ is real-valued Brownian motion, independent of the random potential $\{\mathrm{W}(x) ; x \in \mathbb{R}\}$ and $\beta(0)=\mathbb{W}(0)=0$. We call $\mathbb{X}$ "diffusion with potential $\mathbb{W}$."

We shall assume $\mathbb{W}$ to be a cadlag process (i.e., right continuous with limits on the left), satisfying the following condition of regularity: there exists a coupling for $\mathbb{W}$ and the standard two-sided Brownian motion W such that for all $\mathrm{t} \geq 1$,

$$
\begin{equation*}
\mathbb{P}\left[\sup _{|s| \leq t}|\mathbb{W}(s)-\sigma W(s)| \geq C_{1} \log t\right] \leq \frac{\mathrm{C}_{2}}{\mathrm{t}^{\mathrm{C}_{3}}} \tag{3.1}
\end{equation*}
$$

where $\mathrm{C}_{\mathrm{i}}>0(1 \leq \mathrm{i} \leq 3)$ and $\sigma>0$ are finite constants. As is pointed out in [3], it is easily seen, using diffusion theory, that $\mathbb{X}$ can be represented as

$$
\begin{equation*}
\mathbb{X}(\mathrm{t})=\mathbb{A}^{-1}\left(\mathrm{~B}\left(\mathbb{T}^{-1}(\mathrm{t})\right)\right), \quad \mathrm{t} \geq 0 \tag{3.2}
\end{equation*}
$$

where $\{B(\mathrm{t}) ; \mathrm{t} \geq 0\}$ is Brownian motion starting from 0 , independent of (W, W), and

$$
\begin{equation*}
A(x)=\int_{0}^{x} e^{\mathbb{W}(y)} d y, \quad x \in \mathbb{R}, \text { as defined, } \tag{3.3}
\end{equation*}
$$

$$
\begin{equation*}
\mathbb{T}(r)=\int_{0}^{r} \exp \left[-2 \mathbb{W}\left(\mathbb{A}^{-1}(B(s))\right)\right] d s, \quad r \geq 0, \text { as defined } \tag{3.4}
\end{equation*}
$$

( $\mathbb{A}^{-1}$ and $\mathbb{T}^{-1}$ denote the respective inverse functions of $\mathbb{A}$ and $\mathbb{T}$ ). Actually, $\mathbb{A}$ is the scale function of $\mathbb{X}$, and is for this reason denoted by S in [3]. Observe that under (3.1), the random potential $\mathbb{W}$ is bounded by a finite random constant in each compact interval, which ensures that $\mathbb{A}$ is well defined, with $\mathbb{A}(\infty)=\infty$ and $\mathbb{A}(-\infty)=-\infty$ almost surely.

The Brownian motion $W$ in (3.1) being two-sided, we write

$$
\begin{align*}
H(x) & =\inf \{t>0: W(t)>x\} & & (x \geq 0, \text { as defined }) \\
& =\inf \{t>0: W(t)<x\} & & (x<0, \text { as defined }) \tag{3.5}
\end{align*}
$$

and

$$
\begin{align*}
\mathrm{H}_{-}(\mathrm{x}) & =\inf \{\mathrm{t}>0: \mathrm{W}(-\mathrm{t})>\mathrm{x}\} & & (x \geq 0, \text { as defined }) \\
& =\inf \{\mathrm{t}>0: \mathrm{W}(-\mathrm{t})<\mathrm{x}\} & & (x<0, \text { as defined }) . \tag{3.6}
\end{align*}
$$

The subscript "-" is to insist that (3.6) represents the first hitting time processes for $W$ indexed by $\mathbb{R}_{\mathbf{\prime}}$. Here are the key estimates of the paper.

Proposition 3.1. Assume (3.1). There exist sufficiently large constants $\mathrm{C}_{6}$ and $\mathrm{t}_{0}$, whose values depend on ( $\sigma, \mathrm{C}_{1}, \mathrm{C}_{2}, \mathrm{C}_{3}$ ), such that for

$$
\begin{equation*}
t>t_{0} \quad \text { and } \quad 4 \leq \lambda \leq(\log \log t)^{1 / 2} \tag{3.7}
\end{equation*}
$$

we have

$$
\begin{equation*}
\mathbb{P}\left(\overline{\mathbb{X}}(\mathrm{t})>\lambda \log ^{2} \mathrm{t}\right) \leq \mathrm{C}_{6} \exp \left(-\frac{\pi^{2} \sigma^{2} \lambda}{8}\right) . \tag{3.8}
\end{equation*}
$$

M oreover, under (3.7),

$$
\begin{equation*}
\left\{\overline{\mathbb{X}}(\mathrm{t})>\lambda \log ^{2} \mathrm{t}\right\} \supseteq \mathrm{E}_{3} \cap \mathrm{E}_{4}, \tag{3.9}
\end{equation*}
$$

where

$$
\begin{align*}
\mathrm{E}_{3}=\mathrm{E}_{3}(\lambda, \mathrm{t})= & \left\{\mathrm{H}_{-}\left(-\frac{\log \mathrm{t}}{4 \sigma}\right)>\mathrm{H}_{-}\left(\frac{\log \mathrm{t}}{4 \sigma}\right)\right\} \\
& \cap\left\{\overline{\mathrm{W}}\left(\lambda \log ^{2} \mathrm{t}\right)<\frac{\log \mathrm{t}}{5 \sigma}\right\}  \tag{3.10}\\
& \cap\left\{\mathrm{W}^{\#}\left(\lambda \log ^{2} \mathrm{t}\right)<\left(1-\frac{3}{\lambda}\right) \frac{\log \mathrm{t}}{\sigma}\right\} \text { as defined }
\end{align*}
$$

and $E_{4}=E_{4}(\lambda, t)$ is a measurable event such that

$$
\begin{equation*}
\mathbb{P}\left(E_{4}^{c}\right) \leq C_{6} \exp \left(-\lambda^{2}\right), \tag{3.11}
\end{equation*}
$$

$\mathrm{E}_{4}^{c}$ denoting the complement of $\mathrm{E}_{4}$.
Proposition 3.2. Under (3.1), there exist Iarge $\mathrm{C}_{7}$ and $\mathrm{t}_{0}$, depending on ( $\sigma, \mathrm{C}_{1}, \mathrm{C}_{2}, \mathrm{C}_{3}$ ), such that for all ( $\lambda, \mathrm{t}$ ) satisfying (3.7),

$$
\begin{equation*}
\mathbb{P}\left(\mathbb{X}^{*}(\mathrm{t}) \leq \frac{\log ^{2} \mathrm{t}}{\lambda}\right) \leq \frac{\mathrm{C}_{7}}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right) \tag{3.12}
\end{equation*}
$$

Furthermore, assuming (3.7), there exists $E_{5}=E_{5}(\lambda, t)$ satisfying

$$
\begin{gather*}
\left\{\mathbb{X}^{*}(\mathrm{t}) \leq \frac{\log ^{2} t}{\lambda}\right\} \supseteq \mathrm{E}_{5} \cap\left\{\bar{W}(-v)>\bar{W}(u)+\log ^{4} v\right\}  \tag{3.13}\\
\cap\left\{\sigma W^{\#}(v)>\log t+\log ^{4} v\right\} \\
\mathbb{P}\left(E_{5}^{c}\right) \leq C_{7} \exp \left(-\lambda^{2}\right), \tag{3.14}
\end{gather*}
$$

with $v=(\log t)^{2} / \lambda$ as defined.

Proposition 3.3. Assume (3.1). There exist large $\mathrm{C}_{8}$ and $\mathrm{t}_{0}$, depending on ( $\sigma, \mathrm{C}_{1}, \mathrm{C}_{2}, \mathrm{C}_{3}$ ), such that for

$$
\begin{equation*}
\mathrm{t}>\mathrm{t}_{0} \quad \text { and } \quad 1 \leq \lambda \leq(\log \log \mathrm{t})^{3} \tag{3.15}
\end{equation*}
$$

we have

$$
\begin{equation*}
\mathbb{P}\left(\overline{\mathbb{X}}(\mathrm{t}) \leq \frac{\log ^{2} \mathrm{t}}{\lambda}\right) \leq \frac{\mathrm{C}_{8}}{\sqrt{\lambda}} . \tag{3.16}
\end{equation*}
$$

Furthermore, under (3.15),

$$
\begin{align*}
\left\{\overline{\mathbb{X}}(\mathrm{t}) \leq \frac{\log ^{2} \mathrm{t}}{\lambda}\right\} \supseteq & \mathrm{E}_{6} \cap\left\{\mathrm{H}_{-}\left(\frac{\log \mathrm{t}}{\sqrt{\lambda}}\right)>\mathrm{H}_{-}\left(-\frac{\log \mathrm{t}}{\sigma}\right)\right\} \\
& \cap\left\{\overline{\mathrm{W}}\left(\frac{\log ^{2} \mathrm{t}}{\lambda}\right) \geq \frac{2 \log \mathrm{t}}{\sqrt{\lambda}}\right\} \tag{3.17}
\end{align*}
$$

with $E_{6}=E_{6}(\lambda, t)$ satisfying

$$
\begin{equation*}
\mathbb{P}\left(\mathrm{E}_{6}^{\mathrm{c}}\right) \leq \mathrm{C}_{8} \exp (-\sqrt{\lambda}) \tag{3.18}
\end{equation*}
$$

Although it may not be obvious from their statements, inequalities (3.8), (3.12) and (3.16) are all two-sided, namely, for ( $\lambda, \mathrm{t}$ ) satisfying (3.7) [or (3.15) for Proposition 3.3], we have (with possibly enlarged values of the constants),

$$
\begin{aligned}
\frac{1}{\mathrm{C}_{6}} \exp \left(-\frac{\pi^{2} \sigma^{2} \lambda}{8}\right) & \leq \mathbb{P}\left(\overline{\mathbb{X}}(\mathrm{t})>\lambda \log ^{2} \mathrm{t}\right) \leq \mathrm{C}_{6} \exp \left(-\frac{\pi^{2} \sigma^{2} \lambda}{8}\right) \\
\frac{1}{\mathrm{C}_{7} \sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right) & \leq \mathbb{P}\left(\mathbb{X}^{*}(\mathrm{t}) \leq \frac{\log ^{2} \mathrm{t}}{\lambda}\right) \leq \frac{\mathrm{C}_{7}}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right) \\
\frac{1}{\mathrm{C}_{8} \sqrt{\lambda}} & \leq \mathbb{P}\left(\overline{\mathbb{X}}(\mathrm{t}) \leq \frac{\log ^{2} \mathrm{t}}{\lambda}\right) \leq \frac{\mathrm{C}_{8}}{\sqrt{\lambda}}
\end{aligned}
$$

The proofs of Propositions 3.1-3.3 are postponed until Section 5. They are based on the technical lemmas stated in the next section.
4. Two lemmas. Throughout the paper, unless stated otherwise, $\mathrm{C}_{\mathrm{j}}>0$ ( $9 \leq \mathrm{j} \leq 70$ ) denote (finite) constants, depending on ( $\sigma, \mathrm{C}_{1}, \mathrm{C}_{2}, \mathrm{C}_{3}$ ). We continue using (2.1)-(2.4). Recall the notation for the Brox-type diffusion process $\mathbb{X}$ from (3.2)-(3.4). We assume (3.1). Define

$$
\begin{align*}
\varrho_{\mathrm{x}} & =\inf \{\mathrm{t}>0: \mathrm{B}(\mathrm{t})>\mathrm{x}\}, & & (\mathrm{x} \geq 0, \text { as defined }) \\
& =\inf \{\mathrm{t}>0: \mathrm{B}(\mathrm{t})<\mathrm{x}\}, & & (\mathrm{x}<0, \text { as defined }) \tag{4.1}
\end{align*}
$$

the processes of first hitting times for $B$. Let $\left\{L(t, x) ; t \in \mathbb{R}_{+}, x \in \mathbb{R}\right\}$ be the local time processes of $B$. By the occupation time formula, for $v>0$ and t > 0,

$$
\begin{align*}
\{\overline{\mathbb{X}}(\mathrm{t})>\mathrm{v}\} & =\left\{\int_{0}^{\varrho_{A(v)}} \exp \left[-2 \mathbb{W}\left(\mathbb{A}^{-1}(\mathrm{~B}(\mathrm{~s}))\right)\right] \mathrm{ds}<\mathrm{t}\right\} \\
& =\left\{\int_{-\infty}^{\mathbb{A}(\mathrm{v})} \exp \left(-2 \mathbb{W}\left(\mathbb{A}^{-1}(\mathrm{y})\right)\right) \mathrm{L}\left(\varrho_{\mathbb{A}(v)}, \mathrm{y}\right) \mathrm{dy}<\mathrm{t}\right\}  \tag{4.2}\\
& =\left\{\int_{-\infty}^{v} \exp (-\mathbb{W}(z)) L\left(\varrho_{A(v)}, \mathbb{A}(z)\right) d z<t\right\},
\end{align*}
$$

using a change of variable $y=\mathbb{A}(z)$. Observe that (4.2) is an $\omega$-by- $\omega$ identity.
Accordingly, by writing

$$
\begin{equation*}
I_{1}(v)=\int_{0}^{v} e^{-w(s)} L\left(\varrho_{A(v)}, A(s)\right) d s \text { as defined, } \tag{4.3}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{I}_{2}(\mathrm{v})=\int_{0}^{\infty} \mathrm{e}^{-w(-\mathrm{s})} \mathrm{L}\left(\varrho_{\mathrm{A}(v)}, A(-s)\right) d s \quad \text { as defined } \tag{4.4}
\end{equation*}
$$

we have

$$
\begin{equation*}
\{\overline{\mathbb{X}}(\mathrm{t})>\mathrm{v}\}=\left\{\mathrm{I}_{1}(\mathrm{v})+\mathrm{I}_{2}(\mathrm{v})<\mathrm{t}\right\}, \quad \mathrm{v}>0, \mathrm{t}>0 . \tag{4.5}
\end{equation*}
$$

For brevity, we shall write, throughout the paper,

$$
\begin{aligned}
U_{-}(x) & =-\underline{W}\left(-H_{-}(x)\right)+x \quad \text { as defined } \\
& =\sup _{0 \leq s \leq \inf \{u>0: W(-u)>x\}}(-W(-s))+x, \quad x>0,
\end{aligned}
$$

where W is the Brownian motion in (3.1). We present some technical bounds for $I_{1}(v)$ and $I_{2}(v)$. They will play important roles in the proofs of Propositions 3.1-3.3 in Section 5 .

Lemma 4.1. Assume(3.1). There exists $\mathrm{C}_{9}>0$ such that for all sufficiently large $v$, we can find measurable events $E_{7}=E_{7}(v)$ and $E_{8}=E_{8}(v)$, satisfying

$$
\begin{gather*}
\log \mathrm{I}_{1}(\mathrm{v}) \leq \sigma \mathrm{W}^{\#}(\mathrm{v})+\log ^{4} \mathrm{v} \text { on } \mathrm{E}_{7},  \tag{4.7}\\
\log \mathrm{I}_{1}(\mathrm{v}) \geq \sigma \mathrm{W}^{\#}(\mathrm{v})-\log ^{4} \mathrm{v} \text { on } \mathrm{E}_{8},  \tag{4.8}\\
\mathbb{P}\left(\mathrm{E}_{7}^{\mathrm{c}}\right) \leq \mathrm{C}_{9} \exp \left(-\log ^{2} \mathrm{v}\right)  \tag{4.9}\\
\mathbb{P}\left(\mathrm{E}_{8}^{\mathrm{c}}\right) \leq \mathrm{C}_{9} \exp \left(-\log ^{2} \mathrm{v}\right) \tag{4.10}
\end{gather*}
$$

Lemma 4.2. Assume (3.1). For a large constant $\mathrm{C}_{10}>0$ and all $\mathrm{v}>\mathrm{v}_{0}=$ $v_{0}\left(C_{10}\right)$, there exists a measurable event $E_{9}=E_{9}(v)$ such that,

$$
\begin{equation*}
\log \mathrm{I}_{2}(\mathrm{v}) \leq \sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\log ^{4} \mathrm{v}\right) \quad \text { on } \mathrm{E}_{9} \tag{4.11}
\end{equation*}
$$

$$
\begin{equation*}
\log I_{2}(v) \geq \sigma U_{-}\left(\bar{W}(v)-\log ^{4} v\right) \quad \text { on } E_{9} \cap\left\{\bar{W}(v) \geq 2 \log ^{4} v\right\} \tag{4.12}
\end{equation*}
$$

$$
\begin{equation*}
\mathbb{P}\left(E_{9}^{c}\right) \leq C_{10} \exp \left(-\log ^{2} v\right) \tag{4.13}
\end{equation*}
$$

The proofs of Lemmas 4.1 and 4.2 are presented in Sections 6 and 7, respectively.
5. Proofs of Propositions 3.1-3.3. By admitting Lemmas 4.1 and 4.2 for the moment, we prove Propositions 3.1-3.3 in this section.

Some preliminaries first. For $t>0$, define

$$
\begin{equation*}
\eta_{\mathrm{w}}(\mathrm{t})=\inf \{0 \leq \mathrm{s} \leq \mathrm{t}: \mathrm{W}(\mathrm{~s})=\overline{\mathrm{W}}(\mathrm{t})\} \tag{5.1}
\end{equation*}
$$

the (first) location of the maximum of $W$ over $[0, t]$. Write, for $0 \leq x \leq t$,

$$
\begin{equation*}
\omega_{W}(x, t)=\sup _{0 \leq r \leq s \leq t ; s-r<x}|W(s)-W(r)| \quad \text { as defined, } \tag{5.2}
\end{equation*}
$$

the oscillation modulus of W over [ $0, \mathrm{t}$ ]. Here is a collection of results we shall make use of

Lemma 5.1. For $\mathrm{t}>0, \mathrm{x}>0,0<\mathrm{a}<\mathrm{t}$ and $0<\mathrm{b}<\sqrt{\mathrm{t}}$,

$$
\begin{equation*}
\mathbb{P}\left(\omega_{\mathrm{w}}(\mathrm{a}, \mathrm{t})>\mathrm{b}\right) \leq \mathrm{C}_{11} \frac{\mathrm{t}}{\mathrm{a}} \exp \left(-\frac{\mathrm{b}^{2}}{3 \mathrm{a}}\right) \tag{5.3}
\end{equation*}
$$

$$
\begin{gather*}
\mathbb{P}\left(W^{\#}(t)<x\right) \leq 2 \exp \left(-\frac{\pi^{2} t}{8 x^{2}}\right)  \tag{5.4}\\
\mathbb{P}\left(W^{\#}(t)>x\right) \leq \frac{2 \sqrt{t}}{x} \exp \left(-\frac{x^{2}}{2 t}\right)  \tag{5.5}\\
\mathbb{P}\left(\eta_{W}(t)>t-a\right) \leq \sqrt{\frac{a}{t}} \tag{5.6}
\end{gather*}
$$

Proof. The first inequality is borrowed from a well-known estimate of the Brownian oscillation, and actually more is true (cf. [7], page 24). To see why (5.4) holds, it suffices to observe that according to Lévy's identity, W - $\underline{W}$ is reflecting Brownian motion. Thus the processes $W^{*}$ and $W^{*}$ have the same distribution. Now (5.4) is a straightforward consequence of the exact distribution of $W^{*}$ (1) evaluated by Chung ([5], page 221), and (5.5) follows from the usual estimate of Gaussian tails. Finally, by Lévy's classical arcsine law,

$$
\mathbb{P}\left(\eta_{\mathrm{w}}(1)>1-\mathrm{a}\right)=\frac{2}{\pi} \arcsin \sqrt{\mathrm{a}}
$$

which implies (5.6), using the relation that $\arcsin (y) \leq \pi y / 2$ for $0 \leq y \leq 1$.

Define

$$
\mathrm{C}_{12}=\frac{3}{\mathrm{C}_{3}}+4 \text { as defined, }
$$

where $C_{3}$ is the constant in (3.1). F or large $s$, consider the event
(5.7) $\Omega(s)=\left\{\sup _{|r| \leq \exp \left(C_{12} \log ^{2} s\right)}|\mathbb{W}(r)-\sigma W(r)| \leq \log ^{3} s\right\} \quad$ as defined.

By (3.1),

$$
\begin{equation*}
\mathbb{P}\left(\Omega^{c}(s)\right) \leq C_{2} \exp \left(-3 \log ^{2} s\right) \leq \exp \left(-2 \log ^{2} s\right) \tag{5.8}
\end{equation*}
$$

for all sufficiently large s.
Proof of Proposition 3.1. Recalling (4.3)-(4.5), for all $\mathrm{t}>0$ and large $v>0$,

$$
\begin{aligned}
\mathbb{P}(\overline{\mathbb{X}}(\mathrm{t})>\mathrm{v}) & \leq \mathbb{P}\left(\mathrm{I}_{1}(\mathrm{v})<\mathrm{t}\right) \\
& \leq \mathrm{C}_{9} \exp \left(-\log ^{2} \mathrm{v}\right)+\mathbb{P}\left(\sigma \mathrm{W}^{\#}(\mathrm{v})<\log \mathrm{t}+\log ^{4} \mathrm{v}\right)
\end{aligned}
$$

by means of (4.8) and (4.10). Taking $v=\lambda(\log t)^{2}$ as defined and using (5.4), this yields the upper bound (3.8) in Proposition 3.1.

To prove the lower bound, define $\mathrm{E}_{4}=\mathrm{E}_{7} \cap \mathrm{E}_{9}$ as defined, where $\mathrm{E}_{7}$ and $E_{9}$ are as in Lemmas 4.1 and 4.2, with $v=\lambda(\log t)^{2}$ as defined. It is easily seen from (4.9) and (4.13) that

$$
\mathbb{P}\left(\mathrm{E}_{4}^{\mathrm{c}}\right) \leq \mathbb{P}\left(\mathrm{E}_{7}^{\mathrm{c}}\right)+\mathbb{P}\left(\mathrm{E}_{9}^{\mathrm{c}}\right) \leq \mathrm{C}_{13} \exp \left(-\log ^{2} \mathrm{v}\right) \leq \mathrm{C}_{14} \exp \left(-\lambda^{2}\right)
$$

the last inequality following from (3.7). This yields (3.11). It remains to verify (3.9), with $E_{3}$ defined in (3.10). By (4.7) and (4.11), on $E_{4}, I_{1}(v)+I_{2}(v)$ is smaller than

$$
\exp \left[\sigma \mathrm{W}^{\#}(\mathrm{v})+\log ^{4} \mathrm{v}\right]+\exp \left[\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\log ^{4} \mathrm{v}\right)\right]
$$

where $U_{-}$is defined via (4.6).
On $E_{3}$, we have $\bar{W}(v)+\log ^{4} v \leq(\log t) / 4 \sigma$ and $H_{-}((\log t) / 4 \sigma)<$ $H_{-}(-(\log t) / 4 \sigma)$, hence $U_{-}\left(\bar{W}(v)+\log ^{4} v\right) \leq U_{-}((\log t) / 4 \sigma) \leq(\log t) / 2 \sigma$, whereas $\sigma \mathrm{W}^{\#}(\mathrm{v}) \leq(1-3 / \lambda) \log \mathrm{t}$. Accordingly, on $\mathrm{E}_{3} \cap \mathrm{E}_{4}$,

$$
\begin{aligned}
I_{1}(v)+I_{2}(v) & \leq \exp \left[\left(1-\frac{3}{\lambda}\right) \log t+\log ^{4} v\right]+\exp \left[\frac{\log t}{2}\right] \\
& \leq \exp \left[\left(1-\frac{2}{\lambda}\right) \log t\right]+\sqrt{t} \\
& <t
\end{aligned}
$$

which, in view of (4.5), yields (3.9).
Proof of Proposition 3.3. Take $v=(\log t)^{2} / \lambda$ as defined this time and assume (3.15). Use (4.5) and Lemma 4.2 to see that

$$
\begin{aligned}
\{\bar{X}(\mathrm{t}) \leq \mathrm{v}\} & \supseteq\left\{\log \mathrm{I}_{2}(\mathrm{v}) \geq \log \mathrm{t}\right\} \\
& \supseteq\left\{\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})-\log ^{4} \mathrm{v}\right) \geq \log \mathrm{t} ; \overline{\mathrm{W}}(\mathrm{v}) \geq 2 \sqrt{v}\right\} \cap \mathrm{E}_{9} \\
& \supseteq\left\{\mathrm{H}_{-}\left(\frac{\log \mathrm{t}}{\sqrt{\lambda}}\right)>\mathrm{H}_{-}\left(-\frac{\log \mathrm{t}}{\sigma}\right) ; \overline{\mathrm{W}}\left(\frac{\log ^{2} \mathrm{t}}{\lambda}\right) \geq \frac{2 \log \mathrm{t}}{\sqrt{\lambda}}\right\} \cap \mathrm{E}_{9},
\end{aligned}
$$

which implies (3.17) with $E_{9}$ in place of $E_{6}$.

For the upper bound, use once more Lemmas 4.1 and 4.2 and (4.5) to arrive at the following estimate:

$$
\begin{aligned}
\mathbb{P}(\overline{\mathbb{X}}(\mathrm{t}) \leq \mathrm{v}) \leq & \mathbb{P}\left(\mathrm{I}_{1}(\mathrm{v}) \geq \frac{\mathrm{t}}{2}\right)+\mathbb{P}\left(\mathrm{I}_{2}(\mathrm{v}) \geq \frac{\mathrm{t}}{2}\right) \\
\leq & \mathbb{P}\left(\mathrm{E}_{7}^{c} \cup \mathrm{E}_{9}^{c}\right)+\mathbb{P}\left(\sigma \mathrm{W}^{\#}(\mathrm{v})+\log ^{4} v \geq \log \frac{\mathrm{t}}{2}\right) \\
& +\mathbb{P}\left(\sigma U_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\log ^{4} \mathrm{v}\right) \geq \log \frac{\mathrm{t}}{2}\right) \\
\leq & \mathrm{C}_{15} \exp \left(-\log ^{2} \mathrm{v}\right)+\mathbb{P}\left(\mathrm{W}^{\#}(1) \geq \frac{\sqrt{\lambda}}{\sigma}-\frac{\log 2+\log ^{4} v}{\sigma \sqrt{v}}\right) \\
& +\mathbb{P}\left[U_{-}\left(\overline{\mathrm{W}}(1)+\frac{\log ^{4} v}{\sqrt{v}}\right) \geq \frac{\sqrt{\lambda}}{\sigma}-\frac{\log 2}{\sigma \sqrt{v}}\right]
\end{aligned}
$$

by the scaling property. Since $\mathbb{P}\left(U_{-}(r) \geq a\right)=r / a$ for all $a \geq r>0$, the above is, by (5.5) and (3.15), less than or equal to

$$
\mathrm{C}_{15} \exp \left(-\log ^{2} v\right)+\mathrm{C}_{16} \exp \left(-\frac{\lambda}{2 \sigma^{2}}\right)+\mathbb{E} \frac{\overline{\mathrm{W}}(1)+\left(\log ^{4} v\right) / \sqrt{\mathrm{v}}}{\sqrt{\lambda} / \sigma-(\log 2) / \sigma \sqrt{v}} \leq \frac{\mathrm{C}_{17}}{\sqrt{\lambda}}
$$

yielding (3.16).
The proof of Proposition 3.2 is slightly more technical and needs some preliminaries.

Lemma 5.2. Let $\varrho$ be as in (4.1). For $\mathrm{a}>0, \mathrm{~b}>0$ and $\mathrm{t}>0$,

$$
\begin{aligned}
& \frac{1}{\mathrm{dt}} \mathbb{P}\left(\varrho_{-\mathrm{b}}<\varrho_{a} ; \varrho_{\mathrm{a}} \in \mathrm{dt}\right) \\
& \quad=\sum_{\mathrm{k}=-\infty, \mathrm{k} \neq 0}^{\infty} \frac{2 \mathrm{k}(\mathrm{a}+\mathrm{b})-\mathrm{a}}{\sqrt{2 \pi \mathrm{t}^{3}}} \exp \left(-\frac{(2 \mathrm{k}(\mathrm{a}+\mathrm{b})-\mathrm{a})^{2}}{2 \mathrm{t}}\right)
\end{aligned}
$$

Consequently, for all $a>0$ and $b>0$ such that $a+b \geq 1$,

$$
\begin{align*}
\frac{C_{18}}{a+2 b} \exp \left(-\frac{(a+2 b)^{2}}{2}\right) & \leq \mathbb{P}\left(\varrho_{a}<1 ; \varrho_{-b}<\varrho_{a}\right)  \tag{5.9}\\
& \leq \frac{C_{19}}{a+2 b} \exp \left(-\frac{(a+2 b)^{2}}{2}\right)
\end{align*}
$$

where $\mathrm{C}_{18}>0$ and $\mathrm{C}_{19}>0$ are absol ute constants.
The proof follows from formula 2.1.4(1) in [1], together with the symmetry and density function of $\varrho_{\mathrm{a}}$.

Lemma 5.3. Let $U_{-}$be the process defined in (4.6). For all $0<r<s<y$ and $\mathrm{y} \geq 1$,

$$
\begin{equation*}
\mathbb{P}\left(U_{-}(s)>y ; \bar{W}(-1)>r\right) \leq \frac{C_{19}}{y} \exp \left(-\frac{(2 y-s)^{2}}{2}\right)+(s-r) \tag{5.10}
\end{equation*}
$$

Proof. The probability term on the left-hand side of (5.10) is less than or equal to

$$
\begin{aligned}
& \mathbb{P}\left(U_{-}(s)>y ; \bar{W}(-1)>s\right)+\mathbb{P}(r<\bar{W}(-1) \leq s) \\
& \quad=\mathbb{P}\left(H_{-}(s)<1 ; H_{-}(-(y-s))<H_{-}(s)\right)+\mathbb{P}(r<\bar{W}(-1) \leq s)
\end{aligned}
$$

which yields Lemma 5.3 upon using (5.9) and the fact that the density of $\bar{W}(-1)$ is uniformly bounded by 1 .

Lemma 5.4. Le $\mathbb{A}$ be as in (3.3). For sufficiently large $v$,

$$
\begin{align*}
\mathbb{P}\left(E(v) ; \varrho_{A(v)}<\varrho_{A(-v)}\right) \leq & \mathbb{P}\left(E(v) ; \bar{W}(-v)>\bar{W}(v)-\log ^{4} v\right)  \tag{5.11}\\
& +C_{20} \exp \left(-\log ^{2} v\right) \\
\mathbb{P}\left(E(v) ; \varrho_{A(-v)}<\varrho_{A(v)}\right) \leq & \mathbb{P}\left(E(v) ; \bar{W}(v)>\bar{W}(-v)-\log ^{4} v\right) \\
& +C_{21} \exp \left(-\log ^{2} v\right)
\end{align*}
$$

for any event $E(v)$ (depending on $v$ ) which is measurable with respect to $\{W(x), \mathbb{W}(x) ; x \in \mathbb{R}\}$.

Proof. Since two inequalities bear the same nature, we only prove (5.11). Write $\mathrm{I}_{3}$ for the probability term on the left-hand side of (5.11). Since $\varrho$ is the process of first hitting times for B [which is independent of $(\mathbb{W}, \mathbb{W})$ ], by conditioning on ( $\mathbb{W}, W$ ),

$$
I_{3}=\mathbb{E}\left[\frac{|\mathbb{A}(-v)|}{\mathbb{A}(v)+|\mathbb{A}(-v)|} \mathbb{1}_{E(v)}\right]
$$

Let $\omega_{\mathrm{w}}(\cdot, \cdot)$ and $\eta_{\mathrm{W}}(\cdot)$ be, respectively, as in (5.2) and (5.1). Let $\delta=$ $\exp \left(-\log ^{3} v\right)$ as defined. Define [recalling (5.7)],

$$
\begin{aligned}
\mathrm{E}_{10} & =\left\{\omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})<\log ^{3} \mathrm{v} ; \eta_{\mathrm{W}}(\mathrm{v})<(1-\delta) \mathrm{v}\right\} \cap \Omega(\mathrm{v}) \quad \text { as defined, } \\
\mathrm{F}(\mathrm{v}) & =\left\{\overline{\mathrm{W}}(-\mathrm{v}) \leq \overline{\mathrm{W}}(\mathrm{v})-\frac{\sigma+4}{\sigma} \log ^{3} \mathrm{v}\right\} \quad \text { as defined. }
\end{aligned}
$$

By (5.3), (5.6) and (5.8), for Iarge $v, \mathbb{P}\left(E_{10}^{c}\right) \leq C_{22} \exp \left(-\log ^{2} v\right)$. On the other hand, on $\mathrm{E}_{10}$,

$$
\begin{aligned}
A(v) & =\int_{0}^{\mathrm{v}} \mathrm{e}^{\mathrm{w}(\mathrm{~s})} \mathrm{ds} \geq \int_{0}^{\mathrm{v}} \exp \left(\sigma \mathrm{~W}(\mathrm{~s})-\log ^{3} \mathrm{v}\right) \mathrm{ds} \\
& \geq \int_{\eta_{\mathrm{w}}(\mathrm{v})}^{\eta_{\mathrm{w}}(\mathrm{v})+\delta \mathrm{v}} \exp \left(\sigma \mathrm{~W}(\mathrm{~s})-\log ^{3} \mathrm{v}\right) \mathrm{ds} \\
& \geq \delta \mathrm{v} \exp \left(\sigma \overline{\mathrm{~W}}(\mathrm{v})-\sigma \omega_{\mathrm{w}}(\delta \mathrm{v}, \mathrm{v})-\log ^{3} \mathrm{v}\right) \\
& \geq \mathrm{v} \exp \left(\sigma \overline{\mathrm{~W}}(\mathrm{v})-(\sigma+2) \log ^{3} \mathrm{v}\right)
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
\mathrm{I}_{3} \leq & \mathbb{P}\left(\mathrm{E}(\mathrm{v}) \cap \mathrm{F}^{\mathrm{c}}(\mathrm{v})\right)+\mathrm{C}_{22} \exp \left(-\log ^{2} \mathrm{v}\right) \\
& +\mathbb{E}\left[\frac{|A(-\mathrm{v})|}{\mathrm{vexp}\left(\sigma \overline{\mathrm{~W}}(\mathrm{v})-(\sigma+2) \log ^{3} \mathrm{v}\right)} \mathbb{1}_{\mathrm{E}_{10} \cap \mathrm{~F}(\mathrm{v})}\right]
\end{aligned}
$$

Since $|\mathbb{A}(-\mathrm{v})| \leq \mathrm{v} \exp \left(\sigma \overline{\mathrm{W}}(-\mathrm{v})+\log ^{3} \mathrm{v}\right)$ on $\Omega(\mathrm{v})$, this yields

$$
\begin{aligned}
I_{3} & \leq \mathbb{P}\left(E(v) \cap F^{c}(v)\right)+C_{22} \exp \left(-\log ^{2} v\right)+\exp \left(-\log ^{3} v\right) \\
& \leq \mathbb{P}\left(E(v) ; \bar{W}(-v)>\bar{W}(v)-\log ^{4} v\right)+C_{23} \exp \left(-\log ^{2} v\right)
\end{aligned}
$$

as desired.
Lemma 5.5. There exist universal constants $\mathrm{C}_{24}>0$ and $\mathrm{C}_{25}>0$ such that for all $x \geq 25,|a| \leq 1 / x$ and $|b| \leq 1 / x$,

$$
\begin{align*}
\frac{C_{24}}{x} \exp \left(-x^{2}\right) & \leq \mathbb{P}\left(W^{\#}(1)>x-a ; x>\bar{W}(-1)>\bar{W}(1)-b\right)  \tag{5.13}\\
& \leq \frac{C_{25}}{x} \exp \left(-x^{2}\right) \tag{5.14}
\end{align*}
$$

Proof. Let $I_{4}$ denote the probability term in question. We begin with the proof of (5.14). Clearly, we can assume $a \geq 0$ and $b \geq 0$ without loss of generality. In this case,

$$
\begin{aligned}
I_{4} \leq & \mathbb{P}\left(W^{\#}(1)>x-a ; x>\bar{W}(-1)>\bar{W}(1)-b ; \bar{W}(1) \geq \frac{x}{2}\right) \\
& +\mathbb{P}\left(W^{\#}(1)>x-a ; \bar{W}(1)<\frac{x}{2}\right)
\end{aligned}
$$

The second probability term on the right-hand side is, by (2.6), less than or equal to $\left(C_{26} / x\right) \exp \left(-x^{2}\right)$ (we have used the fact that $3 x / 2 \geq 2 a+\sqrt{2 x}$ ),
whereas the first term is, by independence, (2.6) and (5.5), less than or equal to

$$
\begin{aligned}
\int_{x / 2-b}^{x} & \sqrt{\frac{2}{\pi}} \exp \left(-\frac{u^{2}}{2}\right) \mathbb{P}\left(W^{\#}(1)>x-a ; \bar{W}(1)<u+b\right) d u \\
\leq & \int_{x-a-b}^{x} \sqrt{\frac{2}{\pi}} \exp \left(-\frac{u^{2}}{2}\right) \mathbb{P}\left(W^{\#}(1)>x-a\right) d u \\
& +\int_{x / 2-b}^{x-a-b} \frac{C_{27}}{x} \exp \left(-\frac{u^{2}}{2}-\frac{(2(x-a)-(u+b))^{2}}{2}\right) d u \\
\leq & \frac{C_{28}}{x} \exp \left(-\frac{(x-a-b)^{2}}{2}-\frac{(x-a)^{2}}{2}\right) \\
& +\frac{C_{27}}{x} \exp \left(-\left(x-a-\frac{b}{2}\right)^{2}\right) \int_{-(x-2 a+b) / 2}^{-b / 2} \exp \left(-z^{2}\right) d z \\
\leq & \frac{C_{29}}{x} \exp \left(-x^{2}\right)
\end{aligned}
$$

which yields (5.14).
To prove (5.13), we assume without loss of generality that $\mathrm{a} \leq 0$ and $\mathrm{b} \leq 0$. Now by (2.6),

$$
\begin{aligned}
I_{4} & \geq \int_{x / 2-b}^{x} \sqrt{\frac{2}{\pi}} \exp \left(-\frac{u^{2}}{2}\right) \mathbb{P}\left(W^{\#}(1)>x-a ; \bar{W}(1)<u+b\right) d u \\
& \geq \frac{C_{30}}{x} \exp \left(-x^{2}\right)
\end{aligned}
$$

Lemma 5.5 is proved.
We now prove Proposition 3.2 in two steps, showing first the upper bound in (3.12), then the lower bound in (3.13).

Proof of Proposition 3.2 [Upper bound (3.12)]. As in (4.2) for the onesided case, for all $\mathrm{t}>0$ and $\mathrm{v}>0$,

$$
\begin{equation*}
\left\{\mathbb{X}^{*}(\mathrm{t}) \leq \mathrm{v}\right\}=\left\{\int_{-\mathrm{v}}^{\mathrm{v}} \mathrm{e}^{-\mathrm{w}(\mathrm{z})} \mathrm{L}\left(\varrho_{A(v)} \wedge \varrho_{A(-\mathrm{v})}, \mathbb{A}(\mathrm{z})\right) \mathrm{dz} \geq \mathrm{t}\right\} . \tag{5.15}
\end{equation*}
$$

Let $v=(\log t)^{2} / \lambda$ as defined, with $(\lambda, t)$ satisfying (3.7). Consider

$$
\begin{align*}
& \mathbb{P}\left(\int_{0}^{v} \mathrm{e}^{-\mathbb{W}(z)} \mathrm{L}\left(\varrho_{A(v)} \wedge \varrho_{A(-v)}, A(z)\right) d z \geq \frac{\mathrm{t}}{2}\right) \\
& \quad=\mathbb{P}\left(\int_{0}^{v} \mathrm{e}^{-\mathbb{W}(z)} \mathrm{L}\left(\varrho_{A(v)}, \mathbb{A}(z)\right) \mathrm{dz} \geq \frac{\mathrm{t}}{2} ; \varrho_{A(v)}<\varrho_{A(-v)}\right)  \tag{5.16}\\
& \quad+\mathbb{P}\left(\int_{0}^{v} \mathrm{e}^{-\mathbb{W}(z)} \mathrm{L}\left(\varrho_{A(-v)}, \mathbb{A}(z)\right) \mathrm{dz} \geq \frac{\mathrm{t}}{2} ; \varrho_{A(v)}>\varrho_{A(-v)}\right) \\
& \quad=I_{5}+I_{6} \text { as defined. }
\end{align*}
$$

with obvious notation. Let us bound above $I_{5}$ and $I_{6}$. In what follows, it is to be understood that we work on sufficiently large $t$, though this is not always indicated.

Recall the notation for $I_{1}(v)$ from (4.3). By (4.7) and (4.9),

$$
\begin{aligned}
\mathrm{I}_{5} & =\mathbb{P}\left(\mathrm{I}_{1}(\mathrm{v}) \geq \frac{\mathrm{t}}{2} ; \varrho_{A(v)}<\varrho_{\mathbb{A}(-\mathrm{v})}\right) \\
& \leq \mathbb{P}\left(\sigma \mathrm{W}^{\#}(\mathrm{v}) \geq \log \frac{\mathrm{t}}{2}-\log ^{4} \mathrm{v} ; \varrho_{\mathbb{A}(\mathrm{v})}<\varrho_{\mathbb{A}(-v)}\right)+\mathrm{C}_{9} \exp \left(-\log ^{2} \mathrm{v}\right)
\end{aligned}
$$

Applying Lemma 5.4 to $E(v)=\left\{W^{\#}(v)>\log \left(\frac{t}{2}\right)-\log ^{4} v\right\}$ as defined yields

$$
\begin{aligned}
\mathrm{I}_{5} \leq & \mathbb{P}\left(\sigma \mathrm{W}^{\#}(\mathrm{v}) \geq \log \frac{\mathrm{t}}{2}-\log ^{4} \mathrm{v} ; \overline{\mathrm{W}}(-\mathrm{v})>\overline{\mathrm{W}}(\mathrm{v})-\log ^{4} \mathrm{v}\right) \\
& +\mathrm{C}_{31} \exp \left(-\log ^{2} \mathrm{v}\right) \\
= & \mathbb{P}\left(\mathrm{W}^{\#}(1) \geq \frac{\sqrt{\lambda}}{\sigma}-\frac{\log ^{4} v+\log 2}{\sigma \sqrt{v}} ; \overline{\mathrm{W}}(-1)>\overline{\mathrm{W}}(1)-\frac{\log ^{4} v}{\sqrt{\mathrm{v}}}\right) \\
& +\mathrm{C}_{31} \exp \left(-\log ^{2} v\right) .
\end{aligned}
$$

Since $4 \leq \lambda \leq(\log \log t)^{1 / 2}, v \geq(\log t)^{2} /(\log \log t)^{1 / 2}$ and $\log 2<\log ^{4} v$,

$$
\begin{aligned}
\mathrm{I}_{5} \leq & C_{31} \exp \left(-\log ^{2} v\right)+\mathbb{P}\left(\mathrm{W}^{\#}(1)>\frac{\sqrt{\lambda}}{\sigma}-\frac{2 \log ^{4} v}{\sigma \sqrt{v}} ; \overline{\mathrm{W}}(-1) \geq \frac{\sqrt{\lambda}}{\sigma}\right) \\
& +\mathbb{P}\left(\mathrm{W}^{\#}(1)>\frac{\sqrt{\lambda}}{\sigma}-\frac{2 \log ^{4} v}{\sigma \sqrt{v}} ; \frac{\sqrt{\lambda}}{\sigma}>\bar{W}(-1)>\bar{W}(1)-\frac{\log ^{4} v}{\sqrt{v}}\right)
\end{aligned}
$$

On the right-hand side, the first probability term equals, by independence, $\mathbb{P}\left(\mathrm{W}^{\#}(1)>\sqrt{\lambda} / \sigma-2\left(\log ^{4} \mathrm{v}\right) / \sigma \sqrt{\mathrm{v}}\right) \mathbb{P}(\overline{\mathrm{W}}(-1) \geq \sqrt{\lambda} / \sigma)$, which, according to (5.5) and the Gaussian tail estimate, is smaller than $\left(\mathrm{C}_{32} / \sqrt{\lambda}\right) \exp \left(-\lambda / \sigma^{2}\right)$, whereas the second probability term is bounded above by $\left(C_{33} / \sqrt{\lambda}\right) \exp (-\lambda /$ $\sigma^{2}$ ) by applying Lemma 5.5 to $\mathrm{x}=\sqrt{\lambda} / \sigma, \mathrm{a}=2\left(\log ^{4} \mathrm{v}\right) / \sigma \sqrt{\mathrm{v}}$ and $\mathrm{b}=$ $\left(\log ^{4} v\right) / \sqrt{v}$. Consequently, for all $(t, \lambda)$ satisfying (3.7) and $v=(\log t)^{2} / \lambda$,

$$
\begin{equation*}
\mathrm{I}_{5} \leq \frac{\mathrm{C}_{34}}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right) \tag{5.17}
\end{equation*}
$$

We now estimate the term $I_{6}$ in (5.16), for sufficiently large $t$. Let $\tilde{W}(x)=$ $\mathbb{W}(-x)$ as defined, $W(x)=W(-x)$ as defined, for $x \in \mathbb{R}$, and $\mathrm{B}(\mathrm{t})=-\mathrm{B}(\mathrm{t})$ as defined, for $t \geq 0$. Define $(\tilde{L}, \tilde{\varrho}), \tilde{A}$ and $\tilde{U}_{-}$, which relate to $\tilde{B}, \tilde{W}$ and $\tilde{W}$ exactly in the same ways $(L, \varrho), \mathbb{A}$ and $U_{-}$do to $B, \mathbb{W}$ and $W$. Then

$$
\begin{aligned}
\mathrm{I}_{6} & \leq \mathbb{P}\left(\int_{0}^{\infty} \mathrm{e}^{-w(z)} \mathrm{L}\left(\varrho_{A(-v)}, \mathbb{A}(z)\right) \mathrm{d} z \geq \frac{\mathrm{t}}{2} ; \varrho_{A(v)}>\varrho_{A(-v)}\right) \\
& =\mathbb{P}\left(\int_{0}^{\infty} \mathrm{e}^{-\tilde{W}(-s)} \tilde{L}\left(\tilde{\varrho}_{\tilde{A}(v)}, \tilde{A}(-s)\right) \mathrm{ds} \geq \frac{\mathrm{t}}{2} ; \tilde{\varrho}_{\tilde{A}(v)}<\tilde{\varrho}_{\tilde{A}(-v)}\right) .
\end{aligned}
$$

Since the coupling (3.1) holds for ( $\tilde{W}, \tilde{W}$ ) in place of ( $\mathbb{W}, W$ ), we can apply Lemma 4.2 to (W, W) to arrive at

$$
I_{6} \leq \mathbb{P}\left(\sigma \tilde{U}_{-}\left(\overline{\mathrm{W}}(v)+\log ^{4} v\right) \geq \log \frac{t}{2} ; \tilde{\varrho}_{\tilde{A}(v)}<\tilde{\varrho}_{\tilde{A}(-v)}\right)+\mathrm{C}_{10} \exp \left(-\log ^{2} v\right) .
$$

Applying Lemma 5.4 to ( $\tilde{W}, \tilde{W}, \tilde{\varrho})$ and $E(v)=\left\{\sigma \tilde{U} \quad\left(\bar{W}(\mathrm{v})+\log ^{4} \mathrm{v}\right) \geq\right.$ $\log (\mathrm{t} / 2)$ ) gives

$$
\begin{aligned}
\mathrm{I}_{6} \leq & \mathbb{P}\left(\sigma \tilde{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\log ^{4} v\right) \geq \log \frac{\mathrm{t}}{2} ; \overline{\mathrm{W}}(-\mathrm{v})>\overline{\mathrm{W}}(\mathrm{v})-\log ^{4} v\right) \\
& +\mathrm{C}_{35} \exp \left(-\log ^{2} v\right) \\
= & \mathbb{P}\left(\sigma U_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\log ^{4} v\right) \geq \log \frac{\mathrm{t}}{2} ; \overline{\mathrm{W}}(-\mathrm{v})>\overline{\mathrm{W}}(\mathrm{v})-\log ^{4} v\right) \\
& +\mathrm{C}_{35} \exp \left(-\log ^{2} v\right) \\
\leq & \mathbb{P}\left(U_{-}\left(\overline{\mathrm{W}}(1)+\frac{\log ^{4} v}{\sqrt{v}}\right)>\frac{\sqrt{\lambda}}{\sigma}-\frac{\log ^{4} v}{\sigma \sqrt{v}} ; \overline{\mathrm{W}}(-1)>\overline{\mathrm{W}}(1)-\frac{\log ^{4} v}{\sqrt{v}}\right) \\
& +C_{35} \exp \left(-\log ^{2} v\right)
\end{aligned}
$$

[recalling $\lambda=(\log t)^{2} / v$ as defined]. Write $\tau=\bar{W}(1)+\left(\log ^{4} v\right) / \sqrt{v}$ as defined and $\mathrm{E}_{11}=\left\{2\left(\log ^{4} \mathrm{v}\right) / \sqrt{\mathrm{v}}<\tau<\sqrt{\lambda} / \sigma-\left(\log ^{4} \mathrm{v}\right) / \sigma \sqrt{\mathrm{v}}\right\}$ as defined for brevity. We have

$$
\begin{align*}
& \mathrm{I}_{6} \leq \mathbb{P}\left(\mathrm{U}_{-}(\tau)>\frac{\sqrt{\lambda}}{\sigma}-\frac{\log ^{4} \mathrm{v}}{\sigma \sqrt{\mathrm{v}}} ; \overline{\mathrm{W}}(-1)>\tau-\frac{2 \log ^{4} \mathrm{v}}{\sqrt{\mathrm{v}}} ; \mathrm{E}_{11}\right) \\
&+\mathbb{P}\left(\overline{\mathrm{W}}(1) \geq \frac{\sqrt{\lambda}}{\sigma}-\frac{(\sigma+1) \log ^{4} \mathrm{v}}{\sigma \sqrt{v}} ;\right. \\
&\left.\overline{\mathrm{W}}(-1)>\frac{\sqrt{\lambda}}{\sigma}-\frac{(2 \sigma+1) \log ^{4} \mathrm{v}}{\sigma \sqrt{v}}\right)  \tag{5.18}\\
&+\mathbb{P}\left(\overline{\mathrm{W}}(1) \leq \frac{\log ^{4} v}{\sqrt{v}}\right)+C_{35} \exp \left(-\log ^{2} \mathrm{v}\right)
\end{align*}
$$

Consider the first probability term on the right-hand side, denoted by $\mathrm{I}_{7}$, say. Since $\left\{U_{-}(x) ; x \in \mathbb{R}\right\}$ and $\bar{W}(-1)$ are independent of $\tau$, by conditioning on $\tau$, applying Lemma 5.3 to $\mathrm{s}=\tau, \mathrm{y}=\sqrt{\lambda} / \sigma-\left(\log ^{4} \mathrm{v}\right) / \sigma \sqrt{\mathrm{v}}$ and $\mathrm{r}=\tau-$ $2\left(\log ^{4} v\right) / \sqrt{v}$, recalling that $4 \leq \lambda \leq(\log \log t)^{1 / 2}$ and $v \geq(\log t)^{2} /$ $\log \log t)^{1 / 2}$,

$$
\begin{aligned}
\mathrm{I}_{7} & \leq \frac{\mathrm{C}_{36}}{\sqrt{\lambda}} \mathbb{E}\left[\exp \left(-\frac{(2 \sqrt{\lambda}-\sigma \tau)^{2}}{2 \sigma^{2}}\right) \mathbb{1}_{\mathrm{E}_{11}}\right]+\frac{2 \log ^{4} \mathrm{v}}{\sqrt{\mathrm{~V}}} \\
& \leq \frac{\mathrm{C}_{37}}{\sqrt{\lambda}} \mathbb{E} \exp \left(-\frac{(2 \sqrt{\lambda}-\sigma \overline{\mathrm{W}}(1))^{2}}{2 \sigma^{2}}\right)+\frac{1}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right) .
\end{aligned}
$$

Since $\bar{W}(1)$ is distributed as the modulus of a Gaussian $N(0,1)$ variable, it is easily checked that $\mathrm{I}_{7} \leq\left(\mathrm{C}_{38} / \sqrt{\lambda}\right) \exp \left(-\lambda / \sigma^{2}\right)$. Going back to (5.18), we have bounded above the first probability term on the right-hand side. The third probability term presents no problem, since the density function of $\bar{W}(1)$ is smaller than 1 . For the second, let us note that by the independence of $\bar{W}(1)$ and $\bar{W}(-1)$, and a well-known Gaussian tail property, it is again smaller than $\left(C_{39} / \lambda\right) \exp \left(-\lambda / \sigma^{2}\right)$. Summarizing the situation, we have proved that, for $v=(\log t)^{2} / \lambda$,

$$
\begin{equation*}
\mathrm{I}_{6} \leq \frac{\mathrm{C}_{40}}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right) \tag{5.19}
\end{equation*}
$$

Combining (5.16), (5.17) and (5.19) yields

$$
\mathbb{P}\left(\int_{0}^{v} \mathrm{e}^{-W(z)} \mathrm{L}\left(\varrho_{A(v)} \wedge \varrho_{A(-v)}, \mathbb{A}(z)\right) \mathrm{dz} \geq \frac{\mathrm{t}}{2}\right) \leq \frac{\mathrm{C}_{41}}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right)
$$

[with $v=(\log t)^{2} / \lambda$, of course]. Similarly, we have

$$
\mathbb{P}\left(\int_{-v}^{0} \mathrm{e}^{-W(z)} \mathrm{L}\left(\varrho_{A(v)} \wedge \varrho_{A(-v)}, \mathbb{A}(z)\right) \mathrm{dz} \geq \frac{\mathrm{t}}{2}\right) \leq \frac{\mathrm{C}_{42}}{\sqrt{\lambda}} \exp \left(-\frac{\lambda}{\sigma^{2}}\right)
$$

In view of (5.15), we have proved the desired conclusion in (3.12).
Proof of Proposition 3.2 [Lower bound (3.13)]. Pick large numbers $t>0$ and $v>0$. $B y$ (5.15) and the definition of $I_{1}(v)$,

$$
\left\{\mathbb{X}^{*}(\mathrm{t}) \leq \mathrm{v}\right\} \supseteq\left\{\varrho_{A(v)}<\varrho_{A(-\mathrm{v})} ; \mathrm{I}_{1}(\mathrm{v}) \geq \mathrm{t}\right\} .
$$

Using Lemma 4.1 gives

$$
\left\{\mathbb{X}^{*}(\mathrm{t}) \leq \mathrm{v}\right\} \supseteq\left\{\varrho_{\mathbb{A}(\mathrm{v})}<\varrho_{\mathbb{A}(-\mathrm{v})} ; \sigma \mathrm{W}^{\#}(\mathrm{v})>\log \mathrm{t}+\log ^{4} \mathrm{v}\right\} \cap \mathrm{E}_{8}
$$

with $\mathbb{P}\left(E_{8}^{c}\right) \leq C_{9} \exp \left(-\log ^{2} v\right)$. Define

$$
\mathrm{E}_{12}=\left\{\varrho_{A(v)}>\varrho_{A(-v)}\right\} \cap\left\{\bar{W}(-v)>\bar{W}(v)+\log ^{4} v\right\} \quad \text { as defined. }
$$

Applying (5.12) to $E(v)=\left\{\bar{W}(-v)>\bar{W}(v)+\log ^{4} v\right\}$ yields $\mathbb{P}\left(E_{12}\right) \leq$ $C_{21} \exp \left(-\log ^{2}\right.$ v). Let $E_{5}=E_{8} \cap E_{12}^{c}$ as defined. Obviously, $\mathbb{P}\left(E_{5}^{c}\right) \leq$ $C_{43} \exp \left(-\log ^{2} v\right)$. Moreover,

$$
\begin{aligned}
\left\{\mathbb{X}^{*}(t) \leq v\right\} \supseteq & \left\{\varrho_{A(v)}<\varrho_{A(-v)}\right\} \cap\left\{\sigma W^{\#}(v)>\log t+\log ^{4} v\right\} \cap E_{8} \\
& \cap\left\{\bar{W}(-v)>\bar{W}(v)+\log ^{4} v\right\} \\
= & \left\{\bar{W}(-v)>\bar{W}(v)+\log ^{4} v\right\} \\
& \cap\left\{\sigma W^{\#}(v)>\log t+\log ^{4} v\right\} \cap E_{5} .
\end{aligned}
$$

This proves (3.13) by taking $v=(\log t)^{2} / \lambda$ as defined.
6. Proof of Lemma 4.1. The proof of Lemma 4.1 is based on the following elementary estimates concerning two-dimensional Bessel processes. Recall that a Bessel process of dimension 2 can be realized as the Euclidean modulus of Brownian motion in dimension 2.

Lemma 6.1. Let $\{R(t) ; t \geq 0\}$ be a Bessel process of dimension 2, starting from 0 . For all $0<a<b$ and $x>0$,

$$
\begin{gather*}
\mathbb{P}\left(\inf _{a \leq t \leq b} R(t) \leq x \sqrt{b}\right) \leq 2 x+2 \exp \left(-\frac{x^{2}}{2(1-a / b)}\right)  \tag{6.1}\\
\mathbb{P}\left(\sup _{0<t \leq 1} \frac{R^{*}(t)}{\sqrt{t \log (8 / t)}}>x\right) \leq C_{44} \exp \left(-\frac{x^{2}}{2}\right) \tag{6.2}
\end{gather*}
$$

where $R^{*}$ is as in (2.3).
Proof. To check (6.1), let us note that $R$ is stochastically greater than the linear reflecting Brownian motion |B|. By scaling, the probability term on the left-hand side of (6.1) is less than or equal to

$$
\begin{aligned}
& \mathbb{P}\left(\inf _{a \leq t \leq b}|B(t)| \leq x \sqrt{b}\right) \\
& \quad=\mathbb{P}\left(\inf _{a / b \leq r \leq 1}|B(r)| \leq x\right) \\
& \quad \leq P(|B(1)| \leq 2 x)+\mathbb{P}\left(\sup _{a / b \leq r \leq 1}|B(r)-B(1)| \geq x\right) \\
& \quad=\mathbb{P}(|B(1)| \leq 2 x)+\mathbb{P}\left(\sup _{0 \leq t \leq 1-a / b}|B(t)| \geq x\right),
\end{aligned}
$$

where in the last equality, we have used time reversal for Brownian motion. Now (6.1) follows from the form of Gaussian densities and Mill's ratio for Gaussian tails.

To verify (6.2), recall the well-known estimate

$$
\mathbb{P}\left(R^{*}(t)>y\right) \leq C_{45} \exp \left(-y^{2} / 2 t\right)
$$

(for all positive $y$ and $t$ ), where $C_{45}$ is an absolute constant. Hence, the expression on the left-hand side of (6.2) is less than or equal to

$$
\begin{aligned}
& \sum_{n=1}^{\infty} \mathbb{P}\left(\sup _{1 /(n+1) \leq t \leq 1 / n} \frac{R^{*}(t)}{\sqrt{t \log (8 / t)}}>x\right) \\
& \quad \leq \sum_{n=1}^{\infty} \mathbb{P}\left(R^{*}\left(\frac{1}{n}\right)>\frac{x \sqrt{\log (8 n)}}{\sqrt{n+1}}\right) \\
& \quad \leq C_{45} \sum_{n=1}^{\infty} \exp \left(-\frac{n x^{2} \log (8 n)}{2(n+1)}\right) \\
& \quad \leq C_{45} \sum_{n=1}^{\infty} \exp \left(-\frac{x^{2}}{2}-\frac{x^{2} \log n}{4}\right)
\end{aligned}
$$

which implies (6.2) in case $x \geq 3$. But for $0<x<3$, (6.2) holds trivially, possibly with an enlarged value of $C_{44}$.

The proof of Lemma 4.1 is split into two parts. We first prove the upper estimate in (4.7) with $E_{7}$ defined in (6.4) below and then the lower bound in (4.8) with an appropriate $E_{8}$.

Proof of Lemma 4.1 [upper bound (4.7)]. Fix a large number v. Write as before $\mathrm{L}(\cdot, \cdot)$ for the local time of B. According to the classical Ray-Knight theorem (cf. [28], Theorem VI.52.1), for any given $a>0,\left\{a^{-1} L(\rho(a), a-\operatorname{ta})\right.$; $0 \leq \mathrm{t} \leq 1\}$ is a squared Bessel process of dimension 2, starting from 0. By scaling and the independence of $(\mathbb{W}, W)$ and $B$, letting

$$
\begin{equation*}
R^{2}(t)=\frac{L\left(\varrho_{\mathbb{A}(v)}, \mathbb{A}(v)-t \mathbb{A}(v)\right)}{\mathbb{A}(v)}, \quad 0 \leq t \leq 1 \text {, as defined, } \tag{6.3}
\end{equation*}
$$

$\{R(t) ; 0 \leq t \leq 1\}$ is also a two-dimensional Bessel process with $R(0)=0$ (clearly $R$ is to be taken as the positive square root of $R^{2}$ ), and is, moreover, independent of ( $\mathbb{W}, W$ ) [we shall need the independence later in the proof of (4.8)]. For brevity, write

$$
\mathrm{I}=\log \mathrm{v} \text { as defined, }
$$

("I" for logarithm). Recall $\mathrm{W}^{*}$ and $\Omega$ (v) from (2.3) and (5.7), respectively, and define

$$
\begin{align*}
E_{7}= & \left\{\sup _{0<t \leq 1} \frac{R(t)}{\sqrt{t \log (8 / t)}} \leq v\right\}  \tag{6.4}\\
& \cap\left\{W^{*}(v) \leq \exp \left(I^{2}\right)\right\} \cap \Omega(v) \quad \text { as defined. }
\end{align*}
$$

By means of (6.2), Mill's ratio for Gaussian tails and (5.8),

$$
\mathbb{P}\left(E_{7}^{c}\right) \leq C_{44} \exp \left(-\frac{v^{2}}{2}\right)+4 \exp \left(-\frac{\exp \left(2 I^{2}\right)}{2 v}\right)+\exp \left(-2 I^{2}\right) \leq \exp \left(-I^{2}\right)
$$

This shows $E_{7}$ satisfies (4.9).
Now recall $I_{1}(v)$ from (4.3). On $E_{7}$,

$$
\begin{aligned}
I_{1}(v) & =\int_{0}^{v} \exp (-\mathbb{W}(s)) \mathbb{A}(v) R^{2}\left(\frac{\mathbb{A}(v)-\mathbb{A}(s)}{\mathbb{A}(v)}\right) d s \\
& \leq \int_{0}^{v} \exp \left(-\sigma \mathbb{W}(s)+I^{3}\right) v^{2}(\mathbb{A}(v)-\mathbb{A}(s)) \log \left(\frac{8 \mathbb{A}(v)}{\mathbb{A}(v)-\mathbb{A}(s)}\right) d s .
\end{aligned}
$$

Since on $\mathrm{E}_{7}, \exp (-\sigma \mathrm{W}(\mathrm{s}))(\mathbb{A}(\mathrm{v})-\mathbb{A}(\mathrm{s})) \leq \int_{\mathrm{s}}^{\mathrm{v}} \exp \left(\sigma \mathrm{W}(\mathrm{y})-\sigma \mathrm{W}(\mathrm{s})+\mathrm{I}^{3}\right) \mathrm{dy}$ $\leq \mathrm{vexp}\left(\sigma \mathrm{W}^{\#}(\mathrm{v})+\mathrm{I}^{3}\right)$ for all $0 \leq \mathrm{s} \leq \mathrm{v}$, this yields that, on $\mathrm{E}_{7}$,

$$
\mathrm{I}_{1}(\mathrm{v}) \leq \mathrm{v}^{3} \exp \left(\sigma \mathrm{~W}^{\#}(\mathrm{v})+2 \mathrm{I}^{3}\right) \int_{0}^{\mathrm{v}} \log \left(\frac{8 \mathrm{~A}(\mathrm{v})}{\mathrm{A}(\mathrm{v})-\mathbb{A}(\mathrm{s})}\right) \mathrm{ds} .
$$

On $\quad E_{7}$, for $0 \leq s \leq v, \mathbb{A}(v)-\mathbb{A}(s) \geq(v-s) \exp \left(\sigma \underline{W}(v)-\left.\right|^{3}\right) \geq(v-s)$ $\exp \left(-\sigma \mathrm{W}^{*}(\mathrm{v})-\mathrm{I}^{3}\right)$, whereas $\mathbb{A}(\mathrm{v}) \leq \mathrm{v} \exp \left(\sigma \mathrm{W}^{*}(\mathrm{v})+\mathrm{I}^{3}\right)$. Hence, on $\mathrm{E}_{7}$,

$$
\begin{aligned}
\mathrm{I}_{1}(\mathrm{v}) & \leq \mathrm{v}^{3} \exp \left(\sigma \mathrm{~W}^{\#}(\mathrm{v})+2 \mathrm{I}^{3}\right) \int_{0}^{\mathrm{v}} \log \left(\frac{8 \mathrm{v} \exp \left(2 \sigma \mathrm{~W}^{*}(\mathrm{v})+2 \mathrm{I}^{3}\right)}{\mathrm{v}-\mathrm{s}}\right) \mathrm{ds} \\
& =\mathrm{v}^{4} \exp \left(\sigma \mathrm{~W}^{\#}(\mathrm{v})+2 \mathrm{I}^{3}\right)\left(1+2 \sigma \mathrm{~W}^{*}(\mathrm{v})+2 \mathrm{I}^{3}+\log 8\right)
\end{aligned}
$$

By definition, on $E_{7}, W^{*}(v) \leq \exp \left(I^{2}\right)$, which yields $I_{1}(v) \leq \exp \left(\sigma W^{\#}(v)+\right.$ $\left.\right|^{4}$ ).

Proof of Lemma 4.1 [Lower bound (4.8)]. Fix a large v, and write again $I=\log v$ as defined as before. Write $\delta=\exp \left(-\left.\right|^{2}\right)$ as defined for brevity. From the definition of $W^{\#}$ [cf. (2.4)], for each $t>0$, there exist a couple of random times $\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{t}), \theta_{\mathrm{W}}^{(+)}(\mathrm{t})\right)$ such that $0 \leq \theta_{\mathrm{W}}^{(-)}(\mathrm{t})<\theta_{\mathrm{W}}^{(+)}(\mathrm{t}) \leq \mathrm{t}$ and that

$$
\mathrm{W}^{\#}(\mathrm{t})=\mathrm{W}\left(\theta_{\mathrm{W}}^{(+)}(\mathrm{t})\right)-\mathrm{W}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{t})\right)
$$

Recall $\omega_{\mathrm{w}}$ from (5.2). Let R be as in (6.3). Define

$$
\begin{gathered}
\mathrm{E}_{13}=\left\{\omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v}) \leq \mathrm{I}^{3}\right\} \cap\left\{\mathrm{W}^{\#}(\mathrm{v}) \geq \mathrm{I}^{4}\right\} \text { as defined, } \\
\mathrm{E}_{14}=\left\{\begin{array}{c}
\inf _{\theta_{\mathrm{W}}^{(-)}(\mathrm{v}) \leq \mathrm{s} \leq \theta_{\mathrm{W}}^{(-)}(\mathrm{v})+\delta \mathrm{v}} \mathrm{R}\left(\frac{\mathbb{A}(\mathrm{v})-\mathbb{A}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right) \\
\left.\geq \delta \sqrt{\frac{\mathbb{A}(\mathrm{v})-\mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right)}{\mathbb{A}(\mathrm{v})}}\right\} \text { as defined } \\
\mathrm{E}_{8}=\mathrm{E}_{13} \cap \mathrm{E}_{14} \cap \Omega(\mathrm{v}) \text { as defined. }
\end{array} .\right.
\end{gathered}
$$

Note that, on $\mathrm{E}_{13}$,

$$
\begin{equation*}
\mathrm{v} \geq \theta_{\mathrm{W}}^{(+)}(\mathrm{v}) \geq \theta_{\mathrm{W}}^{(-)}(\mathrm{v})+\delta \mathrm{v} \tag{6.5}
\end{equation*}
$$

which confirms $\theta_{\mathrm{w}}^{(-)}(\mathrm{v}) \leq(1-\delta) \mathrm{v}$. Hence $\mathrm{E}_{13} \cap \mathrm{E}_{14}$ is well defined. According to (5.3) and (5.4),

$$
\begin{equation*}
\mathbb{P}\left(E_{13}^{c}\right) \leq \frac{\mathrm{C}_{11}}{\delta} \exp \left(-\frac{\mathrm{I}^{6}}{3 \delta v}\right)+2 \exp \left(-\frac{\pi^{2} v}{8 I^{8}}\right) \leq \exp \left(-\mathrm{I}^{2}\right) \tag{6.6}
\end{equation*}
$$

On the other hand, since $R$ is independent of ( $\mathbb{W}, W$ ), by conditioning on $(\mathbb{W}, \mathrm{W})$ and applying (6.1) to $\mathrm{a}=\left(\mathbb{A}(\mathrm{v})-\mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})+\delta \mathrm{v}\right)\right) / \mathbb{A}(\mathrm{v}), \mathrm{b}=(\mathbb{A}(\mathrm{v})$ $\left.-\mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right)\right) / \mathbb{A}(\mathrm{v})$ and $\mathrm{x}=\delta$,

$$
\mathbb{P}\left(\mathrm{E}_{14}^{c} \cap \mathrm{E}_{13} \cap \Omega(\mathrm{v})\right) \leq 2 \delta+2 \mathbb{E}\left[\exp \left(-\frac{\delta^{2}}{2} \mathrm{I}_{8}(\mathrm{v})\right) \mathbb{1}_{\mathrm{E}_{13} \cap \Omega(\mathrm{v})}\right]
$$

where

$$
\mathrm{I}_{8}(\mathrm{v})=\frac{\mathbb{A}(\mathrm{v})-\mathbb{A}\left(\theta_{\mathrm{w}}^{(-)}(\mathrm{v})\right)}{\mathbb{A}\left(\theta_{\mathrm{w}}^{(-)}(\mathrm{v})+\delta \mathrm{v}\right)-\mathbb{A}\left(\theta_{\mathrm{w}}^{(-)}(\mathrm{v})\right)} \quad \text { as defined. }
$$

By (6.5), on $\mathrm{E}_{13} \cap \Omega(\mathrm{v})$,

$$
\begin{align*}
\mathbb{A}(\mathrm{v})-\mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right) & =\int_{\theta_{\mathrm{w}}^{(-)}(\mathrm{v})}^{\mathrm{v}} \mathrm{e}^{\mathrm{w}(\mathrm{~s})} \mathrm{ds} \\
& \geq \int_{\theta_{\mathrm{W}}^{(4)}(\mathrm{v})-\delta \mathrm{v}}^{\theta_{(+)}^{(+)}} \exp \left(\sigma \mathrm{W}(\mathrm{~s})-\mathrm{I}^{3}\right) \mathrm{ds}  \tag{6.7}\\
& \geq \delta \mathrm{v} \exp \left(\sigma\left(\mathrm{~W}\left(\theta_{\mathrm{w}}^{(+)}(\mathrm{v})\right)-\omega_{\mathrm{w}}(\delta \mathrm{v}, \mathrm{v})\right)-\mathrm{I}^{3}\right)
\end{align*}
$$

whereas

$$
\begin{aligned}
& \mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})+\delta \mathrm{v}\right)-\mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right) \\
& \quad=\int_{\left.\theta_{\mathrm{w}}^{(()}\right)(\mathrm{v})}^{\theta^{(-)}(\mathrm{v})+\delta \mathrm{v}} \exp (\mathbb{W}(\mathrm{~s})) \mathrm{ds} \\
& \quad \leq \delta \mathrm{v} \exp \left(\sigma\left(\mathbb{W}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right)+\omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})\right)+\mathrm{l}^{3}\right)
\end{aligned}
$$

Hence, on $\mathrm{E}_{13} \cap \Omega(\mathrm{v}), \mathrm{I}_{8}(\mathrm{v}) \geq \exp \left(\sigma \mathrm{W}^{\#}(\mathrm{v})-2 \sigma \omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})-2 \mathrm{I}^{3}\right) \geq \exp \left(\mathrm{I}^{3}\right)$, which yields

$$
\begin{equation*}
\mathbb{P}\left(\mathrm{E}_{14}^{c} \cap \mathrm{E}_{13} \cap \Omega(\mathrm{v})\right) \leq \mathrm{C}_{46} \exp \left(-\mathrm{I}^{2}\right) \tag{6.8}
\end{equation*}
$$

Since by (5.8), $\mathbb{P}\left(\Omega^{c}(v)\right) \leq \exp \left(-\left.2\right|^{2}\right)$, combining (6.6) with (6.8) gives $\mathbb{P}\left(E_{8}^{c}\right)$ $\leq \mathrm{C}_{47} \exp \left(-I^{2}\right)$. This ensures that the event $\mathrm{E}_{8}$ satisfies condition (4.10).

To verify (4.8), observe that on $\mathrm{E}_{13} \cap \Omega(\mathrm{v})$,

$$
\begin{aligned}
\mathrm{I}_{1}(\mathrm{v})= & \int_{0}^{\mathrm{v}} \exp (-\mathbb{W}(\mathrm{s})) \mathbb{A}(\mathrm{v}) \mathrm{R}^{2}\left(\frac{\mathbb{A}(\mathrm{v})-\mathbb{A}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right) \mathrm{ds} \\
\geq & \int_{\theta_{\mathrm{w}}^{(-)}(\mathrm{v})}^{\theta_{\mathrm{w}}^{(-)}(\mathrm{v})+\delta \mathrm{v}} \exp \left(-\sigma \mathrm{W}(\mathrm{~s})-\mathrm{I}^{3}\right) \mathbb{A}(\mathrm{v}) \mathrm{R}^{2}\left(\frac{\mathbb{A}(\mathrm{v})-\mathbb{A}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right) \mathrm{ds} \\
\geq & \delta \mathrm{v} \exp \left(-\sigma \mathrm{W}\left(\theta_{\mathrm{w}}^{(-)}(\mathrm{v})\right)-\sigma \omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})-\mathrm{I}^{3}\right) \mathbb{A}(\mathrm{v}) \\
& \times \inf _{\left.\theta_{\mathrm{w}}^{(-)}(\mathrm{v}) \leq \mathrm{s} \leq \theta_{\mathrm{w}}^{(-)}\right)(\mathrm{v})+\delta \mathrm{v}} \mathrm{R}^{2}\left(\frac{\mathbb{A}(\mathrm{v})-\mathbb{A}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right)
\end{aligned}
$$

Hence, with the aid of (6.7), on $\mathrm{E}_{8}=\mathrm{E}_{13} \cap \mathrm{E}_{14} \cap \Omega(\mathrm{v})$,

$$
\begin{aligned}
\mathrm{I}_{1}(\mathrm{v}) & \geq \delta^{3} \mathrm{v} \exp \left(-\sigma \mathrm{W}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right)-\sigma \omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})-\mathrm{I}^{3}\right)\left(\mathbb{A}(\mathrm{v})-\mathbb{A}\left(\theta_{\mathrm{W}}^{(-)}(\mathrm{v})\right)\right) \\
& \geq \delta^{4} \mathrm{v}^{2} \exp \left(\sigma \mathrm{~W}{ }^{\#}(\mathrm{v})-2 \sigma \omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})-2 \mathrm{I}^{3}\right) \\
& \geq \exp \left(\sigma \mathrm{W}^{\#}(\mathrm{v})-\mathrm{I}^{4}\right)
\end{aligned}
$$

as desired.
Remark 6.2. Our argument also yields the following estimate: for any $0<\varepsilon<1$, there exists a constant $\tilde{C}_{9}$ (possibly depending on $\varepsilon$ ) satisfying that for all large $v$, we can find a measurable event $\tilde{E}_{7}=\tilde{E}_{7}(v)$ with
$\mathbb{P}\left(\tilde{E}_{7}\right) \leq \tilde{C}_{9} \exp \left(-\log ^{2} v\right)$ such that on $\tilde{E}_{7}$,

$$
\begin{aligned}
& \mid \log \sup _{0 \leq \mathrm{s} \leq(1-\varepsilon) \mathrm{v}} \mathrm{e}^{-\mathrm{w}(\mathrm{~s})} \mathrm{L}\left(\varrho_{\mathbb{A}(\mathrm{v})}, A(\mathrm{~A}(\mathrm{~s}))-\sigma \sup _{0 \leq \mathrm{s} \leq(1-\varepsilon) \mathrm{v}, \mathrm{~s} \leq \mathrm{t} \leq \mathrm{v}}(\mathrm{~W}(\mathrm{t})-\mathrm{W}(\mathrm{~s})) \mid\right. \\
& \quad \leq \log ^{4} \mathrm{v},\left|\log _{\mathrm{s} \in \mathbb{Z}_{+}} \mathrm{e}^{-\mathrm{W}(\mathrm{~s})} \mathrm{L}\left(\varrho_{\mathbb{A}(\mathrm{v})}, \mathbb{A}(\mathrm{s})\right)-\sigma \mathrm{W}^{\#}(\mathrm{v})\right| \leq \log ^{4} \mathrm{v}
\end{aligned}
$$

7. Proof of Lemma 4.2. Throughout the section, $v$ is a very large number. Let $L(\cdot, \cdot)$ be as before the local time of $B$, and define the process

$$
Z(t)=\frac{L\left(\varrho_{A(v)},-t \mathbb{A}(v)\right)}{A(v)}, \quad t \geq 0 \text { as defined }
$$

which, by Brownian scaling, is independent of ( $\mathbb{W}, W$ ), and is distributed as $\left\{\mathrm{L}\left(\varrho_{1},-\mathrm{t}\right) ; \mathrm{t} \geq 0\right\}$. According to the Ray-Knight theorem (cf. [28], Theorem VI.52.1), $Z$ is a squared Bessel process of dimension 0 , such that $Z(0)$ has an exponential distribution of mean 2. In particular, 0 is an absorbing state for Z. Let

$$
\begin{equation*}
\zeta=\inf \{t>0: Z(t)=0\} \quad \text { as defined } \tag{7.1}
\end{equation*}
$$

be the absorption time. The next is a collection of elementary facts about $\mathbf{Z}$.
Lemma 7.1. For all positive $t$ and x ,

$$
\begin{gather*}
\mathbb{P}(\zeta>t)=\frac{1}{1+t},  \tag{7.2}\\
\mathbb{P}\left(\inf _{0 \leq s \leq t} Z(s)<x\right) \leq x+\frac{8 t}{x^{2}},  \tag{7.3}\\
\mathbb{P}\left(\sup _{s \geq 0} Z(s)>x\right) \leq \frac{4}{x} . \tag{7.4}
\end{gather*}
$$

Proof. Since $Z$ is distributed as $s \mapsto L\left(\varrho_{1},-s\right)$,

$$
\mathbb{P}(\zeta>\mathrm{t})=\mathbb{P}\left(\varrho_{-\mathrm{t}}<\varrho_{1}\right)=\frac{1}{1+\mathrm{t}}
$$

which yields (7.2). The variable $Z(0)$ having an exponential law with mean 2, its density function is bounded by $1 / 2$. Applying Doob's inequality to the continuous martingale $\{Z(\mathrm{t})-\mathrm{Z}(0)$; $\mathrm{t} \geq 0\}$ gives

$$
\mathbb{P}\left(\sup _{0 \leq s \leq t}|Z(s)-Z(0)|>x\right) \leq \frac{1}{x^{2}} \mathbb{E}(Z(t)-Z(0))^{2}
$$

To compute the expectation term on the right-hand side, note that according again to the Ray-Knight theorem (cf. [28], Theorem VI.52.1), $\mathrm{Z}(\cdot)$ - $\mathrm{Z}(0)$ is a martingale whose associated increasing process equals $\mathrm{t} \mapsto 4 \int_{0}^{\mathrm{t}} \mathrm{Z}(\mathrm{s}) \mathrm{ds}$. Hence

$$
\mathbb{E}(Z(t)-Z(0))^{2}=4 \int_{0}^{t} \mathbb{E}(Z(s)) d s=4 t \mathbb{E} Z(0)=8 t
$$

This shows $\mathbb{P}\left(\sup _{0 \leq s \leq t}|Z(s)-Z(0)|>x\right) \leq 8 t / x^{2}$. As a consequence,

$$
\begin{aligned}
\mathbb{P}\left(\inf _{0 \leq s \leq t} Z(s)<x\right) & \leq \mathbb{P}(Z(0)<2 x)+\mathbb{P}\left(\sup _{0 \leq s \leq t}|Z(s)-Z(0)|>x\right) \\
& \leq x+\frac{8 t}{x^{2}}
\end{aligned}
$$

proving (7.3). To check (7.4), recall (cf. [33]) that for a nonnegative continuous local martingale $M$ tending to 0 , the conditional law of $\sup _{s \geq 0} M$ ( $s$ ) given $M(0)$ is the same as $M(0) / V$, where $V$ denotes a uniform $(0,1)$ variable independent of M . Accordingly,

$$
\mathbb{P}\left(\sup _{s \geq 0} Z(s)>x\right)=\mathbb{P}(Z(0) \geq x)+\mathbb{E}\left(\frac{Z(0)}{x} \mathbb{1}_{\{Z(0)<x\}}\right) \leq \exp \left(-\frac{x}{2}\right)+\frac{2}{x}
$$

which implies (7.4).
Proof of Lemma 4.2. Let v be sufficiently large. Write as before $\mathrm{I}=\log \mathrm{v}$ as defined. Let $W_{-}(t)=W(-t)$ as defined and $\mathbb{W}$ _ $(t)=\mathbb{W}(-t)$ as defined for $t \geq 0$. Hence $\left\{W_{-}(t) ; t \geq 0\right\}$ is a Brownian motion independent of $\{W(t) ; t \geq 0\}$ and $\{B(t) ; t \geq 0\}$. Let

$$
\mathbb{A}_{-}(t)=\int_{0}^{t} \exp \left(\mathbb{W}_{-}(s)\right) d s, \quad t \geq 0 \text { as defined }
$$

which is to $\mathbb{W}$ _ as $\mathbb{A}$ to $\mathbb{W}$. Define

$$
\begin{equation*}
\zeta(v)=\inf \left\{s>0: Z\left(\frac{\mathbb{A}_{-}(s)}{\mathbb{A}(v)}\right)=0\right\} \quad \text { as defined. } \tag{7.5}
\end{equation*}
$$

Let $I_{2}(v)$ be as in (4.4). By the definitions of $Z$ and $A_{-}$, it can be rewritten in a more convenient form:

$$
\begin{align*}
\mathbb{I}_{2}(\mathrm{v}) & =\mathbb{A}(\mathrm{v}) \int_{0}^{\infty} \exp \left(-\mathbb{W}_{-}(\mathrm{s})\right) Z\left(\frac{\mathbb{A}_{-}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right) \mathrm{ds} \\
& =\mathbb{A}(\mathrm{v}) \int_{0}^{\zeta(\mathrm{v})} \exp \left(-\mathbb{W}_{-}(\mathrm{s})\right) Z\left(\frac{\mathbb{A}_{-}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right) \mathrm{ds}  \tag{7.6}\\
& \leq \mathrm{v} \zeta(\mathrm{v}) \exp \left(\overline{\mathbb{W}}(\mathrm{v})+\sup _{0 \leq s \leq \zeta(\mathrm{v})}\left(-\mathbb{W}_{-}(\mathrm{s})\right)\right) \sup _{\mathrm{u} \geq 0} Z(\mathrm{u}), \tag{7.7}
\end{align*}
$$

where in the last inequality, we have used the trivial estimate $\mathbb{A}(\mathrm{v}) \leq$ $v \exp (\overline{\mathbb{W}}(v))$. Consider the events [recalling $\mathrm{H}_{-}$from (3.6), which denotes the process of first hitting times for $W_{-}$]

$$
\begin{gathered}
\mathrm{E}_{15}=\left\{\sup _{\mathrm{u} \geq 0} \mathrm{Z}(\mathrm{u}) \leq \exp \left(\left.\sigma\right|^{4} / 2\right)\right\} \text { as defined, } \\
\mathrm{E}_{16}=\left\{\zeta(\mathrm{v}) \leq \mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\mathrm{I}^{4}\right) \leq \exp \left(\left.4\right|^{2}\right)\right\} \quad \text { as defined. }
\end{gathered}
$$

On $\mathrm{E}_{16} \cap \Omega(\mathrm{v})$,

$$
\begin{aligned}
\overline{\mathbb{W}}(\mathrm{v})+\sup _{0 \leq \mathrm{s} \leq \zeta(\mathrm{v})}\left(-\mathbb{W} \mathbb{W}_{-}(\mathrm{s})\right) & \leq \sigma \overline{\mathrm{W}}(\mathrm{v})+\sigma \sup _{0 \leq \mathrm{s} \leq \mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+1^{4}\right)}\left(-\mathrm{W}_{-}(\mathrm{s})\right)+21^{3} \\
& =\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\mathrm{I}^{4}\right)-\sigma 1^{4}+\left.2\right|^{3},
\end{aligned}
$$

where $U_{-}$is as in (4.6). By (7.7), on $E_{15} \cap E_{16} \cap \Omega(v)$,

$$
\begin{aligned}
\mathrm{I}_{2}(\mathrm{v}) & \leq \mathrm{v} \exp \left(4 \mathrm{I}^{2}\right) \exp \left[\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+{I^{4}}^{4}-\sigma I^{4}+2 \mathrm{I}^{3}\right] \exp \left(\frac{\sigma I^{4}}{2}\right)\right. \\
& \leq \exp \left[\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+I^{4}\right)\right]
\end{aligned}
$$

This proves the upper bound (4.11) with $\mathrm{E}_{9}=\mathrm{E}_{15} \cap \mathrm{E}_{16} \cap \mathrm{E}_{17} \cap \Omega(\mathrm{v})$ as defined, where $\mathrm{E}_{17}$ can be an arbitrary event, which is to be chosen ultimately.

To show the lower bound (4.12), write $\delta=\exp \left(-\left.5\right|^{2}\right)$ as defined for brevity, and define

$$
\mathrm{E}_{18}=\left\{\omega_{\mathrm{w}}(\delta \mathrm{v}, \mathrm{v}) \leq \frac{\mathrm{I}^{4}}{5} ; \eta_{\mathrm{W}}(\mathrm{v}) \leq(1-\delta) \mathrm{v}\right\} \quad \text { as defined }
$$

where $\omega_{\mathrm{W}}(\cdot, \cdot)$ and $\eta_{\mathrm{W}}(\cdot)$ are as in (5.2) and (5.1), respectively. By (5.3) and (5.6),

$$
\begin{equation*}
\mathbb{P}\left(E_{18}^{c}\right) \leq C_{48} \exp \left(-1^{2}\right), \tag{7.8}
\end{equation*}
$$

which has been observed in the proof of Lemma 5.4 in Section 5. On $\mathrm{E}_{18} \cap \Omega(\mathrm{v})$,

$$
\begin{align*}
\mathbb{A}(\mathrm{v}) & =\int_{0}^{\mathrm{v}} \exp (\mathbb{W}(\mathrm{~s})) \mathrm{ds} \geq \int_{\eta_{\mathrm{W}}(\mathrm{v})}^{\eta_{\mathrm{W}}(\mathrm{v})+\delta \mathrm{v}} \exp \left(\sigma \mathrm{~W}(\mathrm{~s})-\mathrm{l}^{3}\right) \mathrm{ds} \\
& \geq \delta \mathrm{v} \exp \left(\sigma \overline{\mathrm{~W}}(\mathrm{v})-\sigma \omega_{\mathrm{W}}(\delta \mathrm{v}, \mathrm{v})-\mathrm{l}^{3}\right)  \tag{7.9}\\
& \geq \exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\frac{\sigma I^{4}}{4}\right)
\end{align*}
$$

Write $\Theta(v)=H_{-}\left(\left(\bar{W}(v)-l^{4}\right)^{+}\right)$as defined for brevity ( $\mathrm{x}^{+}$standing for the positive part of $x$ ), and introduce, for $t>x>0$,

$$
\begin{gathered}
\eta_{-}(t)=\inf \left\{0 \leq s \leq t ;-W_{-}(s)=\sup _{0 \leq r \leq t}\left(-W_{-}(r)\right)\right\} \text { as defined, } \\
\omega_{-}(x, t)=\sup _{0 \leq r \leq s \leq t ; s-r<x}\left|W_{-}(s)-W_{-}(r)\right| \text { as defined }
\end{gathered}
$$

which relate to $-\mathrm{W}_{-}$in the same way as $\eta_{\mathrm{W}}$ and $\omega_{\mathrm{W}}$ do to $W$. Consider the events

$$
\begin{aligned}
& \mathrm{E}_{19}=\{\zeta(\mathrm{v}) \geq \Theta(\mathrm{v})\} \quad \text { as defined, } \\
& \mathrm{E}_{20}=\left\{\mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \leq \exp \left(\frac{\sigma l^{4}}{5}\right)\right\} \text { as defined, } \\
& \mathrm{E}_{21}=\left\{\inf _{0 \leq \mathrm{r} \leq \exp \left(-\sigma I^{4} / 2\right)} \mathrm{Z}(\mathrm{r}) \geq \exp \left(-\frac{\sigma l^{4}}{6}\right)\right\} \text { as defined, } \\
& \mathrm{E}_{22}=\left\{\eta_{-}\left(\mathrm{H}_{-}\left(\mathrm{I}^{4}\right)\right)>\delta \mathrm{v}\right\} \text { as defined, } \\
& \mathrm{E}_{23}=\left\{\omega_{-}\left(\delta \mathrm{v}, \exp \left(\frac{\sigma l^{4}}{5}\right)\right) \leq \frac{1^{4}}{4}\right\} \text { as defined. }
\end{aligned}
$$

Pick a (random) $s \in[0, \Theta(v)]$. On $E_{19} \cap E_{20} \cap\left\{\bar{W}(v)>I^{4}\right\} \cap E_{16} \cap \Omega(v)$,

$$
\begin{aligned}
\mathbb{A}_{-}(\mathrm{s}) & \leq \int_{0}^{\mathrm{H}_{-}\left(\left(\overline{\mathrm{W}}(\mathrm{v})-\mathrm{I}^{4}\right)^{+}\right)} \exp \left(\sigma \mathrm{W}_{-}(\mathrm{z})+\mathrm{I}^{3}\right) \mathrm{d} z \\
& =\int_{0}^{\mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})-\mathrm{I}^{4}\right)} \exp \left(\sigma \mathrm{W}_{-}(\mathrm{z})+\mathrm{I}^{3}\right) \mathrm{d} z \\
& \leq \mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \exp \left(\sigma\left(\overline{\mathrm{W}}(\mathrm{v})-\mathrm{I}^{4}\right)+\mathrm{I}^{3}\right) \\
& \leq \exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\frac{4 \sigma I^{4}}{5}+\mathrm{I}^{3}\right) \\
& \leq \exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\frac{3 \sigma I^{4}}{4}\right)
\end{aligned}
$$

By (7.9), on $E_{18} \cap E_{19} \cap E_{20} \cap\left\{\bar{W}(v)>I^{4}\right\} \cap E_{16} \cap \Omega(v)$, for $s \in[0, \Theta(v)]$,

$$
\begin{gathered}
\mathbb{A}(\mathrm{v}) \geq \exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\frac{\left.\sigma\right|^{4}}{4}\right), \\
\frac{\mathbb{A}_{-}(\mathrm{s})}{\mathbb{A}(\mathrm{v})} \leq \exp \left(-\frac{\left.\sigma\right|^{4}}{2}\right)
\end{gathered}
$$

Using the representation (7.6), on $E_{18} \cap E_{19} \cap E_{20} \cap E_{21} \cap\left\{\bar{W}(v)>\lambda^{4}\right\} \cap$ $\mathrm{E}_{16} \cap \Omega(\mathrm{v})$,

$$
\begin{aligned}
& \mathrm{I}_{2}(\mathrm{v}) \geq \mathbb{A}(\mathrm{v}) \int_{0}^{\Theta(\mathrm{v})} \exp \left(-\sigma \mathrm{W}_{-}(\mathrm{s})-\mathrm{I}^{3}\right) Z\left(\frac{\mathbb{A}_{-}(\mathrm{s})}{\mathbb{A}(\mathrm{v})}\right) \mathrm{ds} \\
& \geq \exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\frac{\sigma I^{4}}{4}\right) \int_{0}^{\Theta(\mathrm{v})} \exp \left(-\sigma \mathrm{W}_{-}(\mathrm{s})-\mathrm{I}^{3}\right) \mathrm{ds} \\
& \inf _{0 \leq \mathrm{r} \leq \exp \left(-\sigma 1^{4} / 2\right)} \mathrm{Z}(\mathrm{r})
\end{aligned}
$$

$$
\geq \exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\frac{5 \sigma l^{4}}{12}-\mathrm{I}^{3}\right) \int_{0}^{\Theta(\mathrm{v})} \exp \left(-\sigma \mathrm{W}_{-}(\mathrm{s})\right) \mathrm{ds}
$$

On $\mathrm{E}_{22} \cap\left\{\overline{\mathrm{~W}}(\mathrm{v}) \geq\left. 2\right|^{4}\right\}$, we have $\eta_{-}(\Theta(\mathrm{v})) \geq \eta_{-}\left(\mathrm{H}_{-}\left(\mathrm{I}^{4}\right)\right)>\delta \mathrm{v}$, whereas on $\mathrm{E}_{20}, \Theta(\mathrm{v}) \leq \mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \leq \exp \left(\left.\sigma\right|^{4} / 5\right)$. Hence, on $\mathrm{E}_{20} \cap \mathrm{E}_{22} \cap \mathrm{E}_{23} \cap\{\bar{W}(\mathrm{v}) \geq$ $\left.21^{4}\right\}$,

Now choose $\mathrm{E}_{17}=\cap_{\mathrm{j}=18}^{23} \mathrm{E}_{\mathrm{j}}$ as defined and let $\mathrm{E}_{9}=\mathrm{E}_{15} \cap \mathrm{E}_{16} \mathrm{E}_{17} \cap \Omega(\mathrm{v})$ as defined. According to (7.10) and (7.11),

$$
\log I_{2}(\mathrm{v}) \geq \sigma U_{-}\left(\bar{W}(\mathrm{v})-I^{4}\right) \quad \text { on } \mathrm{E}_{9} \cap\left\{\overline{\mathrm{~W}}(\mathrm{v}) \geq 21^{4}\right\}
$$

proving the desired lower bound in (4.12).
It remains only to check (4.13), that is $\mathbb{P}\left(E_{9}^{c}\right) \leq C_{10} \exp \left(-I^{2}\right)$. To this end, observe that, by Lemma 7.1,

$$
\begin{equation*}
\mathbb{P}\left(E_{15}^{c}\right) \leq 4 \exp \left(\sigma I^{4} / 2\right) \leq \exp \left(-I^{2}\right) \tag{7.12}
\end{equation*}
$$

$$
\begin{equation*}
\mathbb{P}\left(\mathrm{E}_{21}^{c}\right) \leq \exp \left(-\left.\sigma\right|^{4} / 6\right)+8 \exp \left(-\left.\sigma\right|^{4} / 6\right) \leq \exp \left(-\left.\right|^{2}\right), \tag{7.13}
\end{equation*}
$$

$$
\begin{aligned}
& \int_{0}^{\Theta(v)} \exp \left(-\sigma W_{-}(s)\right) d s \\
& \geq \int_{\eta_{-}(\Theta(\mathrm{v}))-\delta \mathrm{v}}^{\eta_{-}(\Theta(\mathrm{v}))} \exp \left(-\sigma \mathrm{W}_{-}(\mathrm{s})\right) \mathrm{ds}
\end{aligned}
$$

$$
\begin{aligned}
& \left.-\sigma \omega_{-}\left(\delta \mathrm{v}, \exp \left(\frac{\left.\sigma\right|^{4}}{5}\right)\right)\right] \\
& \geq \delta \mathrm{v} \exp \left[\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})-\mathrm{I}^{4}\right)-\sigma\left(\overline{\mathrm{W}}(\mathrm{v})-\mathrm{I}^{4}\right)-\frac{\sigma 1^{4}}{4}\right] \\
& \geq \exp \left[\sigma \mathrm{U}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})-I^{4}\right)-\sigma \overline{\mathrm{W}}(\mathrm{v})+\frac{\sigma ।^{4}}{2}\right] .
\end{aligned}
$$

whereas by applying (5.3) to $\mathrm{a}=\delta \mathrm{v}=\mathrm{v} \exp \left(-\left.5\right|^{2}\right)$, $\mathrm{t}=\exp \left(\left.\sigma\right|^{4} / 5\right)$ and $\mathrm{b}=$ $1^{4} / 4$,

$$
\begin{equation*}
\mathbb{P}\left(E_{23}^{c}\right) \leq \frac{C_{11}}{v} \exp \left(\frac{\sigma I^{4}}{5}+5 I^{2}-\frac{I^{8}}{48 \delta v}\right) \leq C_{49} \exp \left(-I^{2}\right) \tag{7.14}
\end{equation*}
$$

Since $\mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \stackrel{\text { law }}{=} \mathrm{VC}^{2}$, where C stands for a standard Cauchy variable,

$$
\begin{equation*}
\mathbb{P}\left(E_{20}^{c}\right) \leq \pi^{-1} v^{1 / 2} \exp \left(-\left.\sigma\right|^{4} / 10\right) \leq \exp \left(-I^{2}\right) \tag{7.15}
\end{equation*}
$$

To estimate $\mathbb{P}\left(E_{22}^{c}\right)$, recall that for each fixed $t>0$, by Paul Lévy's classical arcsine law, $\eta_{-}(t)$ has the density distribution $\mathbb{P}\left(\eta_{-}(t) \in d x\right) / d x=$ $(1 / \pi \sqrt{x(t-x)}) \mathbb{1}_{\{0<x<t\}}$. Hence

$$
\begin{align*}
\mathbb{P}\left(\mathrm{E}_{22}^{\mathrm{c}}\right) & \leq \mathbb{P}\left(\mathrm{H}_{-}\left(\mathrm{I}^{4}\right)<\sqrt{\delta} \mathrm{v}\right)+\mathbb{P}\left(\eta_{-}(\sqrt{\delta} \mathrm{v}) \leq \delta \mathrm{v}\right) \\
& \leq 2 \exp \left(-\frac{\mathrm{I}^{8}}{2 \sqrt{\delta} \mathrm{v}}\right)+\delta^{1 / 4}  \tag{7.16}\\
& \leq \exp \left(-\mathrm{I}^{2}\right) .
\end{align*}
$$

Recall from (5.8) that $\mathbb{P}\left(\Omega^{c}(v)\right) \leq \exp \left(-\left.2\right|^{2}\right)$. In view of (7.8) and (7.12)-(7.16), the proof of (4.13) is reduced to showing the following estimates:

$$
\begin{align*}
& \mathbb{P}\left(E_{16}^{c} \cap \Omega(v)\right) \leq C_{50} \exp \left(-I^{2}\right),  \tag{7.17}\\
& \mathbb{P}\left(E_{19}^{c} \cap \Omega(v)\right) \leq C_{51} \exp \left(-I^{2}\right) . \tag{7.18}
\end{align*}
$$

Let us check (7.17) first. We have

$$
\begin{aligned}
\mathbb{P}\left(E_{16}^{c} \cap \Omega(v)\right) \leq & \mathbb{P}\left(\zeta(v)>H_{-}\left(\bar{W}(v)+I^{4}\right) ;\right. \\
& \left.\Omega(v) ; H_{-}\left(\bar{W}(v)+I^{4}\right) \leq \exp \left(4 I^{2}\right)\right) \\
& +\mathbb{P}\left(H_{-}\left(\bar{W}(v)+I^{4}\right)>\exp \left(4 I^{2}\right)\right) \\
= & I_{9}+I_{10} \text { as defined, }
\end{aligned}
$$

with obvious notation. By definition,

$$
\begin{aligned}
I_{10} & =\mathbb{P}\left(\bar{W}(v)+I^{4}>\bar{W}\left(-\exp \left(4 I^{2}\right)\right)\right) \\
& \leq \mathbb{P}\left(\bar{W}(v)>\frac{1}{2} \bar{W}\left(-\exp \left(4 I^{2}\right)\right)\right)+\mathbb{P}\left(\bar{W}\left(-\exp \left(4 I^{2}\right)\right)<2 I^{4}\right) \\
& =\mathbb{P}\left(\frac{\bar{W}(v)}{\bar{W}(-v)}>\frac{\exp \left(2 I^{2}\right)}{2 \sqrt{v}}\right)+\mathbb{P}\left(\bar{W}\left(-\exp \left(4 I^{2}\right)\right)<2 I^{4}\right)
\end{aligned}
$$

using the scaling property. Since $\bar{W}(v) / \bar{W}(-v)$ is distributed as the modulus of a standard Cauchy variable, this, jointly considered with the form of Gaussian densities, yields

$$
\begin{equation*}
I_{10} \leq \frac{2 \sqrt{v}}{\pi \exp \left(2 I^{2}\right)}+\frac{2 I^{4}}{\exp \left(2 I^{2}\right)} \leq \exp \left(-I^{2}\right) \tag{7.19}
\end{equation*}
$$

To estimate $I_{9}$, consider the events

$$
\begin{aligned}
& E_{24}=\left\{H_{-}\left(\bar{W}(v)+I^{4}\right)-H_{-}\left(\bar{W}(v)+\frac{I^{4}}{2}\right) \geq \delta v\right\} \text { as defined, } \\
& E_{25}=\left\{\begin{array}{c}
\left.\sup ^{H_{-}\left(\Delta_{W}(v)\right) \leq s \leq H_{-}\left(\Delta_{W}(v)\right)+\delta v}| | W_{-}(s)-\Delta_{W}(v) \left\lvert\,<\frac{I^{4}}{3}\right.\right\} \text { as defined, }
\end{array}\right.
\end{aligned}
$$

with $\Delta_{W}(v)=\bar{W}(v)+I^{4} / 2$ as defined. By the independence of $H_{-}$and $\bar{W}(v)$, and the strong Markov property,

$$
\begin{aligned}
\mathbb{P}\left(\mathrm{E}_{24}^{c}\right) & =\mathbb{P}\left(\mathrm{H}_{-}\left(\frac{I^{4}}{2}\right)<\delta \mathrm{v}\right)=\mathbb{P}\left(\overline{\mathrm{W}}(-\delta \mathrm{v})>\frac{\mathrm{I}^{4}}{2}\right) \\
& \leq 2 \exp \left(-\frac{\mathrm{I}^{8}}{8 \delta \mathrm{v}}\right) \\
& \leq \exp \left(-\mathrm{I}^{2}\right),
\end{aligned}
$$

and

$$
\mathbb{P}\left(E_{25}^{c}\right)=\mathbb{P}\left(\sup _{0 \leq t \leq \delta v}\left|W_{-}(t)\right| \geq \frac{I^{4}}{3}\right) \leq 4 \exp \left(-\frac{I^{8}}{18 \delta v}\right) \leq \exp \left(-I^{2}\right)
$$

Consequently,

$$
I_{9} \leq 2 \exp \left(-I^{2}\right)
$$

$$
\begin{array}{r}
+\mathbb{P}\left(\zeta(v)>H_{-}\left(\bar{W}(v)+I^{4}\right) ; E_{24} ; E_{25} ; \Omega(v)\right.  \tag{7.20}\\
\left.H_{-}\left(\bar{W}(v)+I^{4}\right) \leq \exp \left(4 I^{2}\right)\right) .
\end{array}
$$

By the definitions of $\zeta$ and $\zeta(v)$ [cf. (7.1) and (7.5), respectively], for any $a \geq 0$,

$$
\begin{equation*}
\{\zeta(\mathrm{v})>\mathrm{a}\}=\left\{\mathbb{A}_{-}(\mathrm{a})<\zeta \mathbb{A}(\mathrm{v})\right\} . \tag{7.21}
\end{equation*}
$$

Of course, on $\Omega(\mathrm{v}), \mathbb{A}(\mathrm{v}) \leq \mathrm{vexp}\left(\sigma \overline{\mathrm{W}}(\mathrm{v})+\mathrm{I}^{3}\right)$. On $\mathrm{E}_{24} \cap \mathrm{E}_{25} \cap \Omega(\mathrm{v}) \cap$ $\left\{H_{-}\left(\bar{W}(v)+I^{4}\right) \leq \exp \left(\left.4\right|^{2}\right)\right\}$,

$$
\begin{aligned}
\mathbb{A}_{-}\left(\mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\mathrm{I}^{4}\right)\right) & \geq \int_{\mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+\mathrm{I}^{4} / 2\right)}^{\mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})+1^{4} / 2\right)+\delta v} \exp \left(\sigma \mathrm{~W}_{-}(\mathrm{s})-\mathrm{I}^{3}\right) \mathrm{ds} \\
& \geq \delta v \exp \left(\sigma\left(\overline{\mathrm{~W}}(\mathrm{v})+\frac{\mathrm{I}^{4}}{2}\right)-\frac{\left.\sigma\right|^{4}}{3}-\mathrm{I}^{3}\right) \\
& \geq \mathrm{v} \exp \left(\sigma \overline{\mathrm{~W}}(\mathrm{v})+\frac{\sigma l^{4}}{7}\right) .
\end{aligned}
$$

Going back to (7.20), and then using (7.2),

$$
\begin{aligned}
I_{9} & \leq 2 \exp \left(-I^{2}\right)+\mathbb{P}\left(\zeta>\exp \left(\sigma I^{4} / 7-I^{3}\right)\right) \\
& \leq 2 \exp \left(-I^{2}\right)+\exp \left(-\sigma I^{4} / 7+I^{3}\right) \\
& \leq 3 \exp \left(-I^{2}\right)
\end{aligned}
$$

Since $\mathbb{P}\left(\mathrm{E}_{16}^{c} \cap \Omega(\mathrm{v})\right) \leq \mathrm{I}_{9}+\mathrm{I}_{10}$, this estimate, jointly considered with (7.19), yields (7.17).

To verify (7.18), note from (7.21) that for $b \geq 0$, on $\Omega(v) \cap\left\{H_{-}(b) \leq\right.$ $\left.\exp \left(\left.4\right|^{2}\right)\right\}$,

$$
\begin{aligned}
\left\{\zeta(\mathrm{v}) \leq \mathrm{H}_{-}(\mathrm{b})\right\} & =\left\{\mathbb{A}_{-}\left(\mathrm{H}_{-}(\mathrm{b})\right) \geq \zeta \mathbb{A}(\mathrm{v})\right\} \\
& \subseteq\left\{\exp \left(\sigma \mathrm{b}+\mathrm{I}^{3}\right) \mathrm{H}_{-}(\mathrm{b}) \geq \zeta \mathbb{A}(\mathrm{v})\right\} .
\end{aligned}
$$

Accordingly,

$$
\begin{aligned}
& \mathbb{P}\left(E_{19}^{c} \cap \Omega(\mathrm{v})\right)= \mathbb{P}\left(\zeta(\mathrm{v})<\mathrm{H}_{-}\left(\overline{\mathrm{W}}(\mathrm{v})-\mathrm{I}^{4}\right) ; \overline{\mathrm{W}}(\mathrm{v}) \geq \mathrm{I}^{4} ; \Omega(\mathrm{v})\right) \\
& \leq \mathbb{P}\left(\mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v}))>\exp \left(4 \mathrm{I}^{2}\right)\right) \\
&+\mathbb{P}\left(\exp \left(\sigma \overline{\mathrm{W}}(\mathrm{v})-\sigma \mathrm{I}^{4}+\mathrm{I}^{3}\right) \mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \geq \zeta \mathbb{A}(\mathrm{v})\right. \\
&\left.\Omega(\mathrm{v}) ; \mathrm{H}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \leq \exp \left(4 \mathrm{I}^{2}\right)\right)
\end{aligned}
$$

which, by virtue of (7.8) and (7.9), is less than or equal to

$$
\begin{aligned}
& \mathbb{P}\left(H_{-}(\bar{W}(v))>\exp \left(4 I^{2}\right)\right)+C_{48} \exp \left(-I^{2}\right) \\
& +\mathbb{P}\left(\exp \left(-\sigma I^{4} / 2\right) H_{-}(\bar{W}(v)) \geq \zeta ; E_{18} ; \Omega(v) ; H_{-}(\bar{W}(v)) \leq \exp \left(4 I^{2}\right)\right) \\
& \quad \leq \mathbb{P}\left(H_{-}(\bar{W}(v))>\exp \left(\left.4\right|^{2}\right)\right)+C_{48} \exp \left(-I^{2}\right)+\mathbb{P}\left(\zeta \leq \exp \left(-\frac{\sigma l^{4}}{2}+4 I^{2}\right)\right)
\end{aligned}
$$

Since $H_{-}(\bar{W}(v)) \stackrel{\text { law }}{=} v C^{2}$ ( $C$ denoting a standard Cauchy variable), the above estimate, jointly considered with (7.2), yields

$$
\begin{aligned}
\mathbb{P}\left(\mathrm{E}_{19}^{c} \cap \Omega(\mathrm{v})\right) & \leq \mathrm{C}_{48} \exp \left(-I^{2}\right)+2 \pi^{-1} \mathrm{v}^{1 / 2} \exp \left(-\left.2\right|^{2}\right)+\exp \left(-\frac{\left.\sigma\right|^{4}}{2}+\left.4\right|^{2}\right) \\
& \leq \mathrm{C}_{52} \exp \left(-I^{2}\right)
\end{aligned}
$$

This implies the desired estimate in (7.18), hence Lemma 4.2.
8. Lévy classes for Brox-type diffusions. Theorems $1.6-1.8$ are particular cases of the following general result. Its proof is based on the key estimates in Section 3.

Theorem 8.1. Let $\{\mathbb{W}(x) ; x \in \mathbb{R}\}$ be a cadlag process satisfying (3.1), and $\{\mathbb{X}(\mathrm{t}) ; \mathrm{t} \geq 0\}$ a diffusion process with potential $\mathbb{W}[\mathrm{cf}$. (3.2)]. Let

$$
\begin{aligned}
& J_{1}(f)=\int^{\infty} \frac{f(t)}{t \log t} \exp \left(-\frac{\pi^{2} \sigma^{2}}{8} f(t)\right) d t \text { as defined, } \\
& J_{2}(f)=\int^{\infty} \frac{\sqrt{f(t)}}{t \log t} \exp \left(-\frac{f(t)}{\sigma^{2}}\right) d t \text { as defined, } \\
& J_{3}(f)=\int^{\infty} \frac{d t}{t \sqrt{f(t)} \log t} \text { as defined. }
\end{aligned}
$$

For any nondecreasing function $\mathrm{f}>0$,

$$
\mathbb{P}\left[\mathbb{X}(t)>(\log t)^{2} f(t) \text { i.o. }\right]=\left\{\begin{array} { l l } 
{ 0 }  \tag{8.1}\\
{ 1 } & { \Leftrightarrow } \\
{ J _ { 1 } ( f ) }
\end{array} \left\{\begin{array}{l}
<\infty \\
=\infty
\end{array}\right.\right.
$$

$$
\begin{align*}
& \mathbb{P}\left[\sup _{0 \leq s \leq t}|\mathbb{X}(s)| \leq \frac{(\log t)^{2}}{f(t)} \text { i.o. }\right]=\left\{\begin{array}{lll}
0 & \Leftrightarrow & J_{2}(f)\left\{\begin{array}{l}
<\infty \\
1
\end{array}\right. \\
=\infty,
\end{array}\right.  \tag{8.2}\\
& \mathbb{P}\left[\sup _{0 \leq s \leq t} \mathbb{X}(s) \leq \frac{(\log t)^{2}}{f(t)} \text { i.o. }\right]=\left\{\begin{array}{lll}
0 & \Leftrightarrow & J_{3}(f)\left\{\begin{array}{l}
<\infty \\
1
\end{array}\right. \\
=\infty
\end{array}\right. \tag{8.3}
\end{align*}
$$

In particular, with probability 1,

$$
\begin{aligned}
\limsup _{t \rightarrow \infty} \frac{\mathbb{X}(t)}{(\log t)^{2} \log \log \log t} & =\frac{8}{\pi^{2} \sigma^{2}} \\
\liminf _{t \rightarrow \infty} \frac{\log \log \log t}{(\log t)^{2}} \sup _{0 \leq s \leq t}|\mathbb{X}(s)| & =\frac{1}{\sigma^{2}} \\
\limsup _{t \rightarrow \infty} \frac{(\log \log t)^{a}}{(\log t)^{2}} \sup _{0 \leq s \leq t} \mathbb{X}(s) & = \begin{cases}0, & \text { if } a \leq 2, \\
\infty, & \text { otherwise. }\end{cases}
\end{aligned}
$$

Proof of (8.1). It is known that $\mathbb{X}, \overline{\mathbb{X}}$ and $\mathbb{X}^{*}$ have the same upper functions. This can be shown using an $\omega$-by- $\omega$ argument; compare [7], page 28 , or [22]. We only need to prove (8.1) for $\mathbb{X}$.

As is well known for such results, we only have to limit ourselves to the study of the "critical case,"

$$
\begin{equation*}
\frac{4}{\pi^{2} \sigma^{2}} \log \log \log t \leq f(t) \leq \frac{16}{\pi^{2} \sigma^{2}} \log \log \log t \tag{8.4}
\end{equation*}
$$

for sufficiently large $t$. F or a rigorous justification, compare the pioneer paper of Erdös [11].

In view of (3.8), the convergence part of (8.1) is straightforward. Indeed, pick an arbitrary nondecreasing function $f>0$ satisfying $J_{1}(f)<\infty$. In this case, $f(t)$ clearly tends to infinity. Define the sequence $\left(t_{i}\right)_{i \geq 0}$ by recurrence: choose a large $t_{0}$ and let $\log t_{i+1}=\left(1+1 / f\left(t_{i}\right)\right) \log t_{i}$ as defined for $i \geq 0$. It is easily seen that $t_{i}$ increases to infinity and that $\sum_{i} \exp \left(-\pi^{2} \sigma^{2} f\left(t_{i}\right) / 8\right)<\infty$. By Proposition 3.1,

$$
\begin{aligned}
\mathbb{P}\left(\overline{\mathbb{X}}\left(\mathrm{t}_{\mathrm{i}+1}\right)>\left(\log \mathrm{t}_{\mathrm{i}}\right)^{2} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)\right) & \leq \mathrm{C}_{6} \exp \left(-\frac{\pi^{2} \sigma^{2}\left(\log \mathrm{t}_{\mathrm{i}}\right)^{2} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}{8\left(\log \mathrm{t}_{\mathrm{i}+1}\right)^{2}}\right) \\
& \leq \mathrm{C}_{53} \exp \left(-\frac{\pi^{2} \sigma^{2}}{8} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)\right)
\end{aligned}
$$

which is summable for $i$. By the Borel-Cantelli lemma, almost surely for all sufficiently large $i, \overline{\mathbb{X}}\left(\mathrm{t}_{\mathrm{i}+1}\right) \leq\left(\log \mathrm{t}_{\mathrm{i}}\right)^{2} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)$. Let $\mathrm{t} \in\left[\mathrm{t}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}+1}\right]$, then

$$
\overline{\mathbb{X}}(\mathrm{t}) \leq \overline{\mathbb{X}}\left(\mathrm{t}_{\mathrm{i}+1}\right) \leq\left(\log \mathrm{t}_{\mathrm{i}}\right)^{2} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right) \leq(\log \mathrm{t})^{2} \mathrm{f}(\mathrm{t}),
$$

proving the convergence part in (8.1).
It remains to verify the divergence part. Let $\mathrm{f}>0$ be nondecreasing such that $J_{1}(f)=\infty$. Fix a large $i_{0}$ and let $t_{i}=\exp (\exp (i / \log i))$ for $i \geq i_{0}$. Elementary computations show that

$$
\begin{gather*}
\sum_{i} \exp \left(-\frac{\pi^{2} \sigma^{2}}{8} f\left(t_{i}\right)\right)=\infty,  \tag{8.5}\\
\sum_{i} \exp \left(-f^{2}\left(t_{i}\right)\right)<\infty \tag{8.6}
\end{gather*}
$$

Recall the hitting time process $H_{-}$from (3.6). Write $v_{i}=\left(\log t_{i}\right)^{2} f\left(t_{i}\right)$ as defined for $i \geq i_{0}$. Applying Proposition 3.1 to $\lambda=f\left(t_{i}\right)$ and $t=t_{i}$, there exists a sequence of events $\left(G_{i}\right)_{i \geq i}$, with $\mathbb{P}\left(G_{i}^{c}\right) \leq C_{6} \exp \left(-f^{2}\left(t_{i}\right)\right)$, such that

$$
\begin{equation*}
\left\{\overline{\mathbb{X}}\left(\mathrm{t}_{\mathrm{i}}\right)>\left(\log \mathrm{t}_{\mathrm{i}}\right)^{2} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)\right\} \supseteq \mathrm{F}_{\mathrm{i}} \cap \mathrm{G}_{\mathrm{i}}, \quad \mathrm{i} \geq \mathrm{i}_{0} \tag{8.7}
\end{equation*}
$$

where

$$
\begin{aligned}
\mathrm{F}_{\mathrm{i}}=\left\{\mathrm{H}_{-}\left(-\frac{\log \mathrm{t}_{\mathrm{i}}}{4 \sigma}\right)>\right. & \mathrm{H}_{-}\left(\frac{\log \mathrm{t}_{\mathrm{i}}}{4 \sigma}\right) ; \overline{\mathrm{W}}\left(\mathrm{v}_{\mathrm{i}}\right)<\frac{\log \mathrm{t}_{\mathrm{i}}}{5 \sigma} ; \\
& \left.\mathrm{W}^{\#}\left(\mathrm{v}_{\mathrm{i}}\right)<\left(1-\frac{3}{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}\right) \frac{\log \mathrm{t}_{\mathrm{i}}}{\sigma}\right\} \text { as defined. }
\end{aligned}
$$

Since by (8.6), $\sum_{i} \mathbb{P}\left(\mathrm{G}_{\mathrm{i}}^{\mathrm{i}}\right)<\infty$, we have $\mathbb{P}\left(\mathrm{G}_{\mathrm{i}}\right.$; eventually $)=1$ according to the Borel-Cantelli lemma. In view of (8.7), it remains only to prove that

$$
\begin{equation*}
\mathbb{P}\left(\mathrm{F}_{\mathrm{i}} \mathrm{i} . \mathrm{o} .\right)=1 \tag{8.8}
\end{equation*}
$$

To this end, noting that by the independence of $\mathrm{H}_{-}(\cdot)$ (which depends only on $\left\{\mathrm{W}(\mathrm{t}) ; \mathrm{t} \in \mathbb{R}_{-}\right\}$and ( $\overline{\mathrm{W}}, \mathrm{W}{ }^{\#}$ ) (which depends on $\left\{\mathrm{W}(\mathrm{t}) ; \mathrm{t} \in \mathbb{R}_{+}\right\}$), we have

$$
\begin{aligned}
\mathbb{P}\left(\mathrm{F}_{\mathrm{i}}\right) & =\frac{1}{2} \mathbb{P}\left[\bar{W}\left(\mathrm{v}_{\mathrm{i}}\right)<\frac{\log \mathrm{t}_{\mathrm{i}}}{5 \sigma} ; \mathrm{W}^{\#}\left(\mathrm{v}_{\mathrm{i}}\right)<\left(1-\frac{3}{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}\right) \frac{\log \mathrm{t}_{\mathrm{i}}}{\sigma}\right] \\
& \geq \mathrm{C}_{54} \exp \left(-\frac{\pi^{2} \sigma^{2} \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}{8\left(1-3 / \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)\right)^{2}}\right),
\end{aligned}
$$

by virtue of (2.5). Hence,

$$
\begin{equation*}
\mathbb{P}\left(\mathrm{F}_{\mathrm{i}}\right) \geq \mathrm{C}_{55} \exp \left(-\frac{\pi^{2} \sigma^{2}}{8} f\left(\mathrm{t}_{\mathrm{i}}\right)\right), \quad \mathrm{i} \geq \mathrm{i}_{0} \tag{8.9}
\end{equation*}
$$

which by (8.5) implies $\sum_{i} \mathbb{P}\left(F_{i}\right)=\infty$. To apply the Borel-Cantelli lemma, we have to estimate the second moment. Pick $\mathrm{i}_{0} \leq \mathrm{i}<\mathrm{j}$. Let $\hat{\mathrm{W}}(\mathrm{t})=\mathrm{W}\left(\mathrm{t}+\mathrm{v}_{\mathrm{i}}\right)-$ $W\left(v_{i}\right)$, and $\hat{W}^{\#}(t)=\sup _{0 \leq u \leq s \leq t}(\hat{W}(s)-\hat{W}(u))$. By the independence of Brownian increments,

$$
\begin{aligned}
\mathbb{P}\left(\mathrm{F}_{\mathrm{i}} \cap \mathrm{~F}_{\mathrm{j}}\right) & \leq \mathbb{P}\left[\mathrm{F}_{\mathrm{i}} ; \hat{\mathrm{W}}^{\#}\left(\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}\right) \leq\left(1-\frac{3}{\mathrm{f}\left(\mathrm{t}_{\mathrm{j}}\right)}\right) \frac{\log \mathrm{t}_{\mathrm{j}}}{\sigma}\right] \\
& \leq 2 \mathbb{P}\left(\mathrm{~F}_{\mathrm{i}}\right) \exp \left[-\frac{\pi^{2} \sigma^{2}\left(\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}\right)}{8\left(\log \mathrm{t}_{\mathrm{j}}\right)^{2}\left(1-3 / \mathrm{f}\left(\mathrm{t}_{\mathrm{j}}\right)\right)^{2}}\right],
\end{aligned}
$$

using (5.4). From here, several lines of elementary calculation using (8.4) and (8.9) show that (cf. [11] for details)

$$
\mathbb{P}\left(F_{i} \cap F_{j}\right) \leq \begin{cases}C_{56} \mathbb{P}\left(F_{i}\right) \mathbb{P}\left(F_{j}\right), & \text { if } j-i \geq(\log i)^{2}, \\ C_{57} \mathbb{P}\left(F_{i}\right) j^{-C_{58}}, & \text { if } \log i<j-i<(\log i)^{2}, \\ C_{59} \mathbb{P}\left(F_{i}\right) \exp \left(-C_{60}(j-i)\right), & \text { if } 2 \leq j-i \leq \log i,\end{cases}
$$

which implies

$$
\liminf _{n \rightarrow \infty} \sum_{i=i_{0}}^{n} \sum_{j=i_{0}}^{n} \mathbb{P}\left(F_{i} \cap F_{j}\right) /\left(\sum_{i=i_{0}}^{n} \mathbb{P}\left(F_{i}\right)\right)^{2} \leq C_{61} .
$$

Using the Borel-Cantelli Iemma of [23], $\mathbb{P}\left(\mathrm{F}_{\mathrm{i}}\right.$ i.o. $) \geq 1 / \mathrm{C}_{61}>0$.
We now apply a $0-1$ argument. For any integer $n \geq 0$, let ${ }^{n} W$ and ${ }^{n} W$ _ be the increment processes, of W and $\mathrm{W}_{-}$, respectively, on the time interval [ $n, n+1]$ :

$$
\begin{gathered}
{ }^{n} W=\{W(n+t)-W(n) ; 0 \leq t \leq 1\} \quad \text { as defined, } \\
{ }^{n} W_{-}=\left\{W_{-}(n+t)-W_{-}(n) ; 0 \leq t \leq 1\right\} \quad \text { as defined, }
\end{gathered}
$$

Observe that the random variables (with values in a space of paths) $\left({ }^{n} W,{ }^{n} W_{-}\right)_{n \geq 0}$ are iid. Let $\Sigma$ be a finite permutation on $\mathbb{N}$, that is, for some $\mathrm{N}>0, \Sigma(\mathrm{n})=\mathrm{n}$ whenever $\mathrm{n} \geq \mathrm{N}$. Let ${ }^{\Sigma} \mathrm{W}$ be the Brownian motion obtained by the permutation of the increments of $W$; that is, the increment of ${ }^{\Sigma} W$ on the time interval $[\mathrm{n}, \mathrm{n}+1]$ is ${ }^{\Sigma(n)} \mathrm{W}$. Define similarly ${ }^{\Sigma} \mathrm{W}_{-}$by the permutation of the increments of $W_{-}$. According to our construction, $W(t)={ }^{\Sigma} W(t)$ and $W_{-}(t)={ }^{\Sigma} W_{-}(t)$ for all $t \geq N+1$. Clearly, the event $\left\{F_{i}\right.$ i.o. $\}$ remains unchanged if we replace $W$ and $W_{-}$by ${ }^{\Sigma} W$ and ${ }^{\Sigma} W_{-}$, respectively. As a consequence, we can apply the Hewitt-Saveage 0-1 law, to see that $\left\{F_{i}\right.$ i.o.\} is a trivial event. We have proved (8.8).

Proof of (8.2). The convergence part is a direct consequence of Proposition 3.2, requiring only standard techniques. For more details, compare the proof of (8.1).

To prove the divergence part, let $\mathrm{f}>0$ be a nondecreasing function such that $J_{2}(f)=\infty$. Without loss of generality, we assume

$$
\begin{equation*}
\frac{\sigma^{2}}{2} \log \log \log \mathrm{t} \leq \mathrm{f}(\mathrm{t}) \leq 2 \sigma^{2} \log \log \log \mathrm{t} \tag{8.10}
\end{equation*}
$$

for sufficiently large $t$. Fix a large initial value of $i_{0}$ and define $t_{i}=$ $\exp (\exp (\theta \mathbf{i} / \log \mathrm{i}))$ as defined for $\mathrm{i} \geq \mathrm{i}_{0}$, with $\theta>0$ such that $2 \mathrm{C}_{25} \exp (-\theta / 3)$ $\leq \mathrm{C}_{24}$, where $\mathrm{C}_{24}$ and $\mathrm{C}_{25}$ are the constants in (5.13) and (5.14). Elementary computations using (8.10) give

$$
\begin{gather*}
\sum_{i} f\left(t_{i}\right)^{-1 / 2} \exp \left(-\frac{f\left(t_{i}\right)}{\sigma^{2}}\right)=\infty  \tag{8.11}\\
\sum_{i} \exp \left(-f^{2}\left(t_{i}\right)\right)<\infty \tag{8.12}
\end{gather*}
$$

Write $v_{i}=\left(\log t_{i}\right)^{2} / f\left(t_{i}\right)$ as defined. Applying Proposition 3.2 to $t=t_{i}$ and $\lambda=\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)$,

$$
\begin{equation*}
\left\{\mathbb{X}^{*}\left(\mathrm{t}_{\mathrm{i}}\right) \leq \mathrm{v}_{\mathrm{i}}\right\} \supseteq \mathrm{F}_{\mathrm{i}} \cap \mathrm{G}_{\mathrm{i}}, \quad \mathrm{i} \geq \mathrm{i}_{0}, \tag{8.13}
\end{equation*}
$$

where

$$
\begin{aligned}
\mathrm{F}_{\mathrm{i}}=\left\{\frac{\log \mathrm{t}_{\mathrm{i}}}{\sigma}>\overline{\mathrm{W}}\left(-\mathrm{v}_{\mathrm{i}}\right)>\right. & \overline{\mathrm{W}}\left(\mathrm{v}_{\mathrm{i}}\right)+\log ^{4} \mathrm{v}_{\mathrm{i}} ; \mathrm{W}\left(\mathrm{v}_{\mathrm{i}}\right)>-\frac{2 \log \mathrm{t}_{\mathrm{i}}}{\sigma} ; \\
& \left.\frac{\log \mathrm{t}_{\mathrm{i}+1}}{\sigma} \geq \mathrm{W}^{\#}\left(\mathrm{v}_{\mathrm{i}}\right)>\frac{\log \mathrm{t}_{\mathrm{i}}}{\sigma}+\frac{\log ^{4} \mathrm{v}_{\mathrm{i}}}{\sigma}\right\} \text { as defined, }
\end{aligned}
$$

and $\mathbb{P}\left(G_{i}^{c}\right) \leq C_{7} \exp \left(-f^{2}\left(t_{i}\right)\right)$. Using (8.12), $\sum_{i} \mathbb{P}\left(G_{i}^{c}\right)<\infty$, which according to the Borel-Cantelli lemma implies $\mathbb{P}\left(\mathrm{G}_{\mathrm{i}}\right.$; eventually) $=1$. In view of (8.13), we only have to show that

$$
\begin{equation*}
\mathbb{P}\left(\mathrm{F}_{\mathrm{i}} \mathrm{i} . \mathrm{o} .\right)=1 \tag{8.14}
\end{equation*}
$$

Note that $\log t_{i+1} / \log t_{i}-1 \sim \theta / \log i$ and that $\sigma^{2}(\log i) / 3 \leq f\left(t_{i}\right) \leq$ $3 \sigma^{2} \log \mathrm{i}$ for $\mathrm{i} \geq \mathrm{i}_{0}$. Applying scaling and Lemma 5.5 , it is readily seen that

$$
\begin{align*}
& \mathbb{P}\left(\mathrm{F}_{\mathrm{i}}\right) \geq \mathbb{P}\left(\frac{\log \mathrm{t}_{\mathrm{i}}}{\sigma}>\overline{\mathrm{W}}\left(-\mathrm{v}_{\mathrm{i}}\right)>\overline{\mathrm{W}}\left(\mathrm{v}_{\mathrm{i}}\right)+\log ^{4} \mathrm{v}_{\mathrm{i}} ;\right. \\
&\left.\mathrm{W}^{\#}\left(\mathrm{v}_{\mathrm{i}}\right)>\frac{\log \mathrm{t}_{\mathrm{i}}+\log ^{4} \mathrm{v}_{\mathrm{i}}}{\sigma}\right) \\
&-\mathbb{P}\left(\frac{\log \mathrm{t}_{\mathrm{i}+1}}{\sigma}>\overline{\mathrm{W}}\left(-\mathrm{v}_{\mathrm{i}}\right)>\overline{\mathrm{W}}\left(\mathrm{v}_{\mathrm{i}}\right)+\log ^{4} \mathrm{v}_{\mathrm{i}} ;\right. \\
&\left.\mathrm{W} \#\left(\mathrm{v}_{\mathrm{i}}\right)>\frac{\log \mathrm{t}_{\mathrm{i}+1}}{\sigma}\right) \\
& \geq \frac{\mathrm{C}_{24} \sigma}{\sqrt{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}} \exp \left(-\frac{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}{\sigma^{2}}\right)-\frac{\mathrm{C}_{25} \sigma}{\sqrt{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}}  \tag{8.15}\\
&\left.\quad \times \exp \left(-\frac{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}{\sigma^{2}}-\theta / 3\right)-2 \exp \left(-\frac{2 \mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}{\sigma^{2}}\right) \leq-\frac{2 \log \mathrm{t}_{\mathrm{i}}}{\sigma}\right) \\
& \geq \frac{\mathrm{C}_{62}}{\sqrt{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}} \exp \left(-\frac{\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)}{\sigma^{2}}\right),
\end{align*}
$$

by our choice of $\theta$. To apply the Borel-Cantelli lemma, let $\hat{W}(s)=W\left(s+v_{i}\right)$ $-W\left(v_{i}\right)$ as defined and $\hat{W}(-s)=W\left(-s-v_{i}\right)-W\left(-v_{i}\right)$ as defined for $s \geq 0$. Let $\mathrm{i}_{0} \leq \mathrm{i} \leq \mathrm{j}-2$. On $\mathrm{F}_{\mathrm{i}} \cap \mathrm{F}_{\mathrm{j}}$,

$$
\begin{aligned}
\hat{W}^{\#}\left(v_{j}-v_{i}\right) & =\sup _{v_{i} \leq s \leq r \leq v_{j}}(W(r)-W(s)) \\
& \geq W^{\#}\left(v_{j}\right)-W^{\#}\left(v_{i}\right) \\
& \geq \frac{\log t_{j}-\log t_{i+1}}{\sigma}
\end{aligned}
$$

and

$$
\begin{aligned}
\hat{W}\left(v_{j}-v_{i}\right) & =\sup _{v_{i} \leq r \leq v_{j}} W(r)-W\left(v_{i}\right) \\
& \leq \bar{W}\left(v_{j}\right)+\frac{2 \log t_{i}}{\sigma} \\
& \leq \bar{W}\left(-v_{j}\right)+\frac{2 \log t_{i}}{\sigma} \\
& \leq \bar{W}\left(-\left(v_{j}-v_{i}\right)\right)+\bar{W}\left(-v_{i}\right)+\frac{2 \log t_{i}}{\sigma} \\
& \leq \bar{W}\left(-\left(v_{j}-v_{i}\right)\right)+\frac{3 \log t_{i}}{\sigma} .
\end{aligned}
$$

By the independence of Brownian increments,

$$
\begin{align*}
\mathbb{P}\left(F_{i} \cap F_{j}\right) \leq & \mathbb{P}\left(F_{i} ; \hat{W}^{\#}\left(v_{j}-v_{i}\right) \geq \frac{\log t_{j}-\log t_{i+1}}{\sigma} ;\right. \\
& \left.\hat{W}\left(-\left(v_{j}-v_{i}\right)\right) \geq \hat{W}\left(v_{j}-v_{i}\right)-\frac{3 \log t_{i}}{\sigma}\right)  \tag{8.16}\\
= & \mathbb{P}\left(F_{i}\right) I_{11},
\end{align*}
$$

where

$$
\begin{aligned}
\mathrm{I}_{11}= & \mathbb{P}\left(\mathrm{W}^{\#}\left(\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}\right) \geq \frac{\log \mathrm{t}_{\mathrm{j}}-\log \mathrm{t}_{\mathrm{i}+1}}{\sigma} ;\right. \\
& \left.\overline{\mathrm{W}}\left(-\left(\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}\right)\right) \geq \overline{\mathrm{W}}\left(\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}\right)-\frac{3 \log \mathrm{t}_{\mathrm{i}}}{\sigma}\right) \quad \text { (as defined) } \\
= & \mathbb{P}\left(\mathrm{W}^{\#}(1) \geq \frac{\log \mathrm{t}_{\mathrm{j}}-\log \mathrm{t}_{\mathrm{i}+1}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}} ; \overline{\mathrm{W}}(-1) \geq \overline{\mathrm{W}}(1)-\frac{3 \log \mathrm{t}_{\mathrm{i}}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}\right) .
\end{aligned}
$$

From here, the proof becomes routine. Indeed, for $\mathrm{j}-\mathrm{i} \geq(\log \mathrm{i})^{2}$,

$$
\begin{aligned}
& \mathrm{I}_{11} \leq \mathbb{P}\left(\mathrm{W}^{\#}(1) \geq \frac{\log \mathrm{t}_{\mathrm{j}}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}-\frac{\log \mathrm{t}_{\mathrm{i}+1}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}\right. \\
&\left.\frac{\log \mathrm{t}_{\mathrm{j}}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}} \geq \overline{\mathrm{W}}(-1) \geq \overline{\mathrm{W}}(1)-\frac{3 \log \mathrm{t}_{\mathrm{i}}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}\right) \\
&+ \mathbb{P}\left(\overline{\mathrm{W}}(-1)>\frac{\log \mathrm{t}_{\mathrm{j}}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}\right) \\
& \times \mathbb{P}\left(\mathrm{W}^{\#}(1) \geq \frac{\log \mathrm{t}_{\mathrm{j}}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}-\frac{\log \mathrm{t}_{\mathrm{i}+1}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}\right) \\
& \leq \frac{\mathrm{C}_{63} \sigma}{\sqrt{\mathrm{f}\left(\mathrm{t}_{\mathrm{j}}\right)}} \exp \left(-\frac{\mathrm{f}\left(\mathrm{t}_{\mathrm{j}}\right)}{\sigma^{2}}\right)+\frac{\mathrm{C}_{64} \sigma}{\mathrm{f}\left(\mathrm{t}_{\mathrm{j}}\right)} \exp \left(-\frac{\mathrm{f}\left(\mathrm{t}_{\mathrm{j}}\right)}{\sigma^{2}}\right) \\
& \leq \mathrm{C}_{65} \mathbb{P}\left(\mathrm{~F}_{\mathrm{j}}\right)
\end{aligned}
$$

using Lemma 5.5 and (8.15). For $2 \leq \mathrm{j}-\mathrm{i}<(\log \mathrm{i})^{2}$,

$$
\begin{aligned}
\mathrm{I}_{11} & \leq \mathbb{P}\left(W^{\#}(1) \geq \frac{\log \mathrm{t}_{\mathrm{j}}-\log \mathrm{t}_{\mathrm{i}+1}}{\sigma \sqrt{\mathrm{v}_{\mathrm{j}}-\mathrm{v}_{\mathrm{i}}}}\right) \\
& \leq \begin{cases}\mathrm{C}_{66} \mathrm{i}^{-\mathrm{C}_{67}}, & \text { if } \log \mathrm{i}<\mathrm{j}-\mathrm{i}<(\log \mathrm{i})^{2}, \\
\mathrm{C}_{68} \exp \left(-\mathrm{C}_{69}(\mathrm{j}-\mathrm{i})\right), & \text { if } 2 \leq \mathrm{j}-\mathrm{i} \leq \log \mathrm{i},\end{cases}
\end{aligned}
$$

which, jointly considered with (8.16) and (8.17), implies that

$$
\liminf _{n \rightarrow \infty} \sum_{i=i_{0}}^{n} \sum_{j=i_{0}}^{n} \mathbb{P}\left(F_{i} \cap F_{j}\right) /\left(\sum_{i=i_{0}}^{n} \mathbb{P}\left(F_{i}\right)\right)^{2} \leq C_{70} .
$$

According to the Borel-Cantelli Iemma in [23], $\mathbb{P}\left(F_{i}\right.$ i.o. $) \geq 1 / C_{70}>0$. Applying a $0-1$ argument readily yields (8.14), and hence (8.2).

The proof of (8.3) is very similar to (and a lot easier than) that of (8.2), using Proposition 3.3 instead of Proposition 3.2. We feel free to omit the details.
9. Skorokhod embedding. This brief section is devoted to a Sko-rokhod-type embedding of Sinai's RWRE. The result (cf. Proposition 9.1 below) is not new, since it was previously stated in [17] (cf. also [29]). The proof is given here in full detail.

Let $\left\{S_{n}\right\}_{n \geq 0}$ be Sinai's random walk in random environment $\Xi=\left\{\xi_{j}\right\}_{j \in \mathbb{N}}$, as in Section 1.1. Assume (1.9). From the environment $\Xi$, we define $\left\{W_{\Xi}(y)\right.$; $\mathrm{y} \in \mathbb{R}\}$ as a step function with $\mathrm{W}_{\Xi}(0)=0$, which is flat in each interval $[n, n+1$ ) (for $n \in \mathbb{Z}$ ), with jumps

$$
\mathbb{W}_{\Xi}(n)-\mathbb{W}_{\Xi}(n-)=\log \frac{1-\xi_{n}}{\xi_{n}} \quad \text { as defined. }
$$

Consider the diffusion process $\{\mathbb{X}(\mathrm{t}), \mathrm{t} \geq 0\}$ with random potential $\mathbb{W}_{\Xi}$, defined via (3.2)-(3.4), with $\mathbb{W}_{\equiv}$ in the place of $\mathbb{W}$. According to [16], Theorem 3.1, condition (1.9) ensures that $\limsup _{\mathrm{t} \rightarrow \infty} \mathbb{X}(\mathrm{t})=\infty$ and $\liminf _{\mathrm{t} \rightarrow \infty} \mathbb{X}(\mathrm{t})=$ $-\infty$ almost surely. Define the sequence of stopping times $\left\{\mu_{\mathrm{n}}, \mathrm{n} \geq 0\right\}$ by $\mu_{0}=0$ and
$\mu_{\mathrm{n}}=\inf \left\{\mathrm{t}>\mu_{\mathrm{n}-1}:\left|\mathbb{X}(\mathrm{t})-\mathbb{X}\left(\mu_{\mathrm{n}-1}\right)\right|=1\right\}, \quad \mathrm{n}=1,2, \ldots \quad$ as defined.
Proposition 9.1. Under (1.9), the two sequences $\left\{\mathbb{X}\left(\mu_{n}\right)\right\}_{n \geq 0}$ and $\left\{S_{n}\right\}_{n \geq 0}$ have the same distributions. Furthermore, $\left\{\mu_{\mathrm{n}}-\mu_{\mathrm{n}-1}\right\}_{\mathrm{n} \geq 1}$ are iid variables, distributed as $\inf \{\mathrm{t}>0$ : $|\mathrm{B}(\mathrm{t})|=1\}$.

Remark 9.2. Condition (1.9) in the proposition is only to ensure that $\mu_{\mathrm{n}}$ ( $\mathrm{n} \geq 1$ ) are well defined.

The proof of the proposition is based on the following result which we have learnt from [34].

Lemma 9.3 (Yor [34]). Let $\varrho$ be the process of first hitting times of $B$ as in (4.1). For all positive $a$ and $b$,

$$
\int_{0}^{\varrho_{\mathrm{a}} \wedge \varrho_{-\mathrm{b}}}\left(\mathrm{a}^{-2} \mathbb{1}_{\{\mathrm{B}(\mathrm{~s})>0\}}+\mathrm{b}^{-2} \mathbb{1}_{\{\mathrm{B}(\mathrm{~s})<0\}}\right) \mathrm{ds} \stackrel{\operatorname{law}}{=} \inf \{\mathrm{t}<0:|\mathrm{B}(\mathrm{t})|=1\} .
$$

Proof of Lemma 9.3. For $t>0$, let $\mathrm{B}^{+}(\mathrm{t})$ and $\mathrm{B}^{-}(\mathrm{t})$ be, respectively, the positive and negative parts of $B(t)$. By Tanaka's formula,

$$
\begin{aligned}
& a^{-1} B^{+}(t)+b^{-1} B^{-}(t) \\
& \quad=\int_{0}^{t}\left(a^{-1} \mathbb{1}_{\{B(s)>0\}}-b^{-1} \mathbb{1}_{\{B(s)<0\}}\right) d B(s)+\frac{a^{-1}+b^{-1}}{2} L(t, 0),
\end{aligned}
$$

where $L(\cdot, \cdot)$ is as before the local time of $B$. This is a Skorokhod-type reflection equation. By Lemma VI.2.1 of [27], there exists one-dimensional reflecting Brownian motion, denoted by $\gamma$, such that for all $\mathrm{t} \geq 0, \mathrm{a}^{-1} \mathrm{~B}^{+}(\mathrm{t})+$ $\mathrm{b}^{-1} \mathrm{~B}^{-}(\mathrm{t})=\gamma(\mathrm{D}(\mathrm{t}))$, where

$$
\mathrm{D}(\mathrm{t})=\int_{0}^{\mathrm{t}}\left(\mathrm{a}^{-2} \mathbb{1}_{\{\mathrm{B}(\mathrm{~s})>0\}}+\mathrm{b}^{-2} \mathbb{1}_{\{\mathrm{B}(\mathrm{~s})<0\}}\right) \mathrm{ds} \text { as defined. }
$$

Hence

$$
\mathrm{D}\left(\varrho_{\mathrm{a}} \wedge \varrho_{-\mathrm{b}}\right)=\inf \{\mathrm{t}>0: \gamma(\mathrm{t})=1\}
$$

as desired.
Proof of Proposition 9.1. Define $\mathbb{A}_{\Xi}$ and $\mathbb{T}_{\equiv}$ as in (3.2)-(3.4), with $\mathbb{W}_{\equiv}$ in place of $\mathbb{W}$. Since $\mathbb{X}$ is a diffusion process with scale function $\mathbb{A}_{\Xi}$,

$$
\mathbb{P}\left(\mathbb{X}\left(\mu_{\mathrm{n}}\right)=\mathrm{i}+1 \mathbb{X}\left(\mu_{\mathrm{n}-1}\right)=\mathrm{i} ; \Xi\right)=\frac{\mathbb{A}_{\Xi}(\mathrm{i})-\mathbb{A}_{\Xi}(\mathrm{i}-1)}{\mathbb{A}_{\Xi}(\mathrm{i}+1)-\mathbb{A}_{\Xi}(\mathrm{i}-1)}=\xi_{\mathrm{i}},
$$

the last equality following from the definition of $\mathbb{W}_{\Xi}$. This identifies the distributions of $\left\{\mathbb{X}\left(\mu_{n}\right), n \geq 0\right\}$ and $\left\{S_{n}, n \geq 0\right\}$.

It remains to prove the second part of the proposition. The independence of $B$ and $\Xi$ plays an important role. Conditionally on $\Xi$ and on the event $\left\{\mathbb{X}\left(\mu_{n-1}\right)=\mathrm{i}\right\}$ [hence $\mathrm{B}\left(\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}-1}\right)\right)=\mathbb{A}_{\Xi}(\mathrm{i})$ ],

$$
\mu_{n}-\mu_{-1}=\inf \left\{s>0: B\left(\mathbb{T}_{\Xi}^{-1}\left(s+\mu_{n-1}\right)\right)=\mathbb{A}_{\Xi}(\mathrm{i}+1) \text { or } \mathbb{A}_{\Xi}(\mathrm{i}-1)\right\},
$$

which in words means that $\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}}\right)$ is the first exit time of B from the interval $\left[\mathbb{A}_{\Xi}(\mathrm{i}-1), \mathbb{A}_{\Xi}(\mathrm{i}+1)\right]$ after time $\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}-1}\right)$; thus equivalently,

$$
\begin{aligned}
& \mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}}\right)-\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}-1}\right) \\
& \quad=\inf \left\{\mathrm{t}>0: \mathrm{B}\left(\mathrm{t}+\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}-1}\right)\right)=\mathbb{A}_{\Xi}(\mathrm{i}+1) \text { or } \mathbb{A}_{\Xi}(\mathrm{i}-1)\right\} .
\end{aligned}
$$

Accordingly,

$$
\begin{aligned}
\mu_{\mathrm{n}}-\mu_{\mathrm{n}-1}= & \int_{\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}-1}\right)}^{\mathbb{T} \Xi^{-1}\left(\mu_{\mathrm{n}}\right)} \exp \left[-2 \mathbb{W}_{\Xi}\left(\mathbb{A}_{\Xi}^{-1}(\mathrm{~B}(\mathrm{~s}))\right)\right] \mathrm{ds} \\
= & \int_{\mathbb{T}_{\Xi}^{-1}\left(\mu_{\mathrm{n}-1}\right)}^{\mathbb{T} \Xi^{1}\left(\mu_{\mathrm{n}}\right)}\left(\exp \left(-2 \mathbb{W}_{\Xi}(\mathrm{i})\right) \mathbb{1}_{\left\{\mathrm{B}(\mathrm{~s})>\mathbb{A}_{\Xi}(\mathrm{i})\right\}}\right. \\
& \left.+\exp \left(-2 \mathbb{W}_{\Xi}(\mathrm{i}-1)\right) \mathbb{1}_{\left\{\mathrm{B}(\mathrm{~s})<\mathbb{A}_{\Xi}(\mathrm{i})\right\}}\right) \mathrm{ds} \\
= & \int_{0}^{\hat{\varrho}}\left(\exp \left(-2 \mathbb{W}_{\Xi}(\mathrm{i})\right) \mathbb{1}_{\{\hat{\mathrm{B}}(\mathrm{~s})>0\}}+\exp \left(-2 \mathbb{W}_{\Xi}(\mathrm{i}-1)\right) \mathbb{1}_{\{\hat{\mathrm{B}}(\mathrm{~s})<0\}}\right) \mathrm{ds},
\end{aligned}
$$

where $\hat{B}(t)=B\left(t+\mathbb{T}_{\Xi}^{-1}\left(\mu_{n-1}\right)\right)-\mathbf{B}\left(\mathbb{T}_{\Xi}^{-1}\left(\mu_{n-1}\right)\right)$ (for $t \geq 0$ ) as defined and $\hat{\varrho}=\inf \left\{\mathrm{t}>0: \hat{\mathrm{B}}(\mathrm{t})=\exp \left(\mathbb{W}_{\Xi}(\mathrm{i})\right)\right.$ or $\left.-\exp \left(\mathbb{W}_{\Xi}(\mathrm{i}-1)\right)\right\}$ as defined. By Lemma 9.3 , for any n , conditionally on $\Xi,\left\{\mathbb{W}_{\Xi}\left(\mu_{\mathrm{n}-1}\right)=\mathrm{i}\right\}$ and $\left(\mu_{1}, \ldots, \mu_{\mathrm{n}-1}\right)$, the variable $\mu_{\mathrm{n}}-\mu_{\mathrm{n}-1}$ is distributed as the first hitting time at 1 of standard reflecting Brownian motion. This yields the second part of the proposition.
10. Proofs of Theorems 1.3-1.5. We say a few words about the proofs of Theorems 1.3-1.5, which are now consequences of Proposition 9.1 and Theorem 8.1. Let us, for example, prove the first half of Theorem 1.3 (the rest of Theorems $1.3-1.5$ can be verified exactly in the same spirit). As was pointed out in Section 8, we only have to characterize the upper functions of $\max _{0 \leq k \leq n} S_{k}$ [where $\left\{S_{n}\right\}_{n \geq 0}$ is of course Sinai's simple RWRE whose environment $\exists$ satisfies (1.9)].

We use the embedding described in Section 8, and continue adopting the same notation. By the second part of Proposition 9.1, $\left\{\mu_{n}\right\}_{n \geq 1}$ is the partial sum process of a sequence of iid variables with common mean 1 and finite variance, say $c^{2}$. According to the usual law of the iterated logarithm,

$$
\limsup _{n \rightarrow \infty} \frac{\left|\mu_{n}-n\right|}{c(2 n \log \log n)^{1 / 2}}=1 \quad \text { a.s. }
$$

In particular, almost surely for all large $n$,

$$
\mathrm{n}-\mathrm{n}^{2 / 3} \leq \mu_{\mathrm{n}} \leq \mathrm{n}+\mathrm{n}^{2 / 3}
$$

To verify the convergence part of Theorem 1.3, let $\left\{a_{n}\right\}_{n \geq 1}$ be a sequence of positive nondecreasing numbers, such that

$$
\begin{equation*}
\sum_{\mathrm{n}} \frac{\mathrm{a}_{\mathrm{n}}}{\mathrm{n} \log \mathrm{n}} \exp \left(-\frac{\pi^{2} \sigma^{2}}{8} \mathrm{a}_{\mathrm{n}}\right)<\infty \tag{10.1}
\end{equation*}
$$

As in (8.4) in the continuous-time setting, we assume without loss of generality that

$$
\frac{4}{\pi^{2} \sigma^{2}} \log \log \log n \leq a_{n} \leq \frac{16}{\pi^{2} \sigma^{2}} \log \log \log n
$$

Define the nondecreasing function $f(t)=a_{[t / 2]}-1$ as defined. Condition (10.1) guarantees $\mathrm{J}_{1}(\mathrm{f})<\infty$, where $\mathrm{J}_{1}$ is defined in Theorem 8.1. By (8.1), with probability 1 , for all large $t, \sup _{0 \leq s \leq t} \mathbb{X}(s) \leq(\log t)^{2} f(t)$. Consequently, for all large n,

$$
\begin{aligned}
\max _{0 \leq \mathrm{k} \leq \mathrm{n}} \mathbb{X}\left(\mu_{\mathrm{k}}\right) & \leq \sup _{0 \leq \mathrm{s} \leq \mu_{n}} \mathbb{X}(\mathrm{~s})+1 \\
& \leq\left(\log \mu_{\mathrm{n}}\right)^{2} \mathrm{f}\left(\mu_{\mathrm{n}}\right)+1 \\
& \leq\left(\log \left(\mathrm{n}+\mathrm{n}^{2 / 3}\right)\right)^{2}\left(\mathrm{a}_{\mathrm{n}}-1\right)+1 \\
& <(\log \mathrm{n})^{2} \mathrm{a}_{\mathrm{n}},
\end{aligned}
$$

which, in view of Proposition 9.1, implies the convergence part of Theorem 1.3.
11. Weak convergence and limit distribution. Although the main object of the paper is to study almost sure asymptotics, our approach allows us to recover, as a by-product, the weak convergence of $\max _{0 \leq k \leq n} S_{k}$ (as well as its explicit limit distribution) stated in Theorem A (cf. Section 1.1). In view of the embedding in Proposition 9.1, we only have to treat the continuous-time case: the diffusion process $\mathbb{X}$ with random potential $\mathbb{W}$ [cf. (3.2) for definition]. Recall $\mathbb{T}, \mathbb{A}, H_{-}$from (3.3)-(3.6), $\varrho$ from (4.1), and $\overline{\mathbb{X}}$ and $W^{\#}$ from (2.1)-(2.4). Write for all $v>0$,

$$
\begin{equation*}
\overline{\mathbb{X}}^{-1}(\mathrm{v})=\inf \{\mathrm{t}>0: \overline{\mathbb{X}}(\mathrm{t})>\mathrm{v}\} \quad \text { as defined } \tag{11.1}
\end{equation*}
$$

Note that $\overline{\mathbb{X}}^{-1}(\mathrm{v})$ is nothing else by $\mathbb{T}\left(\varrho_{\mathbb{A}(\mathrm{v})}\right)$.
Proposition 11.1. Let $\{\mathbb{W}(x) ; x \in \mathbb{R}\}$ be a cadlag process satisfying (3.1), and $\{\mathbb{X}(\mathrm{t}) ; \mathrm{t} \geq 0\}$ a diffusion process with potential $\mathbb{W}[\mathrm{cf}$. (3.2)]. As v goes to infinity,

$$
\begin{equation*}
\frac{1}{\sqrt{v}}\left[\frac{\log \overline{\mathbb{X}}^{-1}(\mathrm{v})}{\sigma}-\mathrm{W}^{\#}(\mathrm{v}) \vee \mathrm{U}_{-}(\overline{\mathrm{W}}(\mathrm{v}))\right] \rightarrow 0 \tag{11.2}
\end{equation*}
$$

in probability, where $U_{\text {_ }}$ is defined in (4.6).
Corollary 11.2. We have

$$
\begin{aligned}
\frac{\sigma^{2}}{(\log \mathrm{t})^{2}} \overline{\mathbb{X}}(\mathrm{t}) \xrightarrow{\operatorname{law}} \Lambda=\left(\mathrm{W}^{\#}(1) \vee \mathrm{U}_{-}(\overline{\mathrm{W}}(1))\right)^{-2} & \\
\mathrm{t} & \rightarrow \infty \text { (as defined }) .
\end{aligned}
$$

Moreover, the limit law is characterized either by distribution function or by Laplace transform:

$$
\begin{align*}
\mathbb{P}(\Lambda<x)= & 1-\sum_{k=0}^{\infty} \frac{8}{(2 k+1)^{2} \pi^{2}} \exp \left(-\frac{(2 k+1)^{2} \pi^{2} x}{8}\right), \quad x>0  \tag{11.3}\\
& \mathbb{E} \exp (-\lambda \Lambda)=\frac{\tanh \sqrt{2 \lambda}}{\sqrt{2 \lambda}}, \quad \lambda>0
\end{align*}
$$

Remark 11.3. From (11.3) or (11.4), it is noted that $\Lambda$ is distributed as the last zero of $B$ before exiting from $[-1,1]$.

Proof of Corollary 11.2. The weak convergence follows from (11.1) and (11.2) and from the scaling property. It remains to verify (11.3)-(11.4). Observe that $\mathbb{P}\left(U_{-}(r)<x\right)=(x-r) / x$ for all $x>r$. Since $U_{-}$is indepen-
dent of ( $\left.\mathrm{W}^{\#}, \overline{\mathrm{~W}}\right)$,

$$
\begin{aligned}
\mathbb{P}(\mathbb{W} & \left.\#(1) \vee U_{-}(\bar{W}(1))<t\right) \\
& =\mathbb{P}\left(W^{\#}(1)<t ; U_{-}(\overline{\mathrm{W}}(1))<\mathrm{t}\right) \\
& =\mathbb{E}\left(\frac{\mathrm{t}-\overline{\mathrm{W}}(1)}{\mathrm{t}} 1_{\left\{\mathrm{W}^{\#}(1) \leq \mathrm{t}\right\}}\right) \\
& =\int_{0}^{\mathrm{t}} \frac{2}{\mathrm{t}} \sum_{\mathrm{k}=0}^{\infty} \frac{\mathrm{t}-\mathrm{a}}{\mathrm{t}} \exp \left(-\frac{(2 \mathrm{k}+1)^{2} \pi^{2}}{8 \mathrm{t}^{2}}\right) \cos \left(\left(\mathrm{k}+\frac{1}{2}\right) \frac{\pi \mathrm{a}}{\mathrm{t}}\right) \mathrm{da},
\end{aligned}
$$

the last equality due to Theorem 2.1. This yields (11.3). The Laplace transform (11.4) can be obtained using (11.3) and the well-known relation

$$
\sum_{\mathrm{k}=0}^{\infty} \frac{1}{(2 \mathrm{k}+1)^{2}+\mathrm{x}^{2}}=\frac{\pi}{4 \mathrm{x}} \tanh \left(\frac{\pi \mathrm{x}}{2}\right), \quad \mathrm{x}>0 .
$$

This completes the proof of Corollary 11.2.
Proof of Proposition 11.1. By (4.5), $\bar{X}^{-1}(v)=I_{1}(v)+I_{2}(v)$ for all $v>0$, which implies $\log \left(I_{1}(v) \vee I_{2}(v)\right) \leq \log \overline{\mathbb{X}}^{-1}(\mathrm{v}) \leq \log \left(I_{1}(\mathrm{v}) \vee \mathrm{I}_{2}(\mathrm{v})\right)+\log 2$. The proof of the proposition is thus reduced to showing the following estimate: for any $\mathrm{a}>0$ and $\varepsilon>0$, there exists $\mathrm{v}_{0}>0$ such that for all $\mathrm{v} \geq \mathrm{v}_{0}$,

$$
\begin{equation*}
\mathbb{P}\left(\left|\log \left(\mathrm{I}_{1}(\mathrm{v}) \vee \mathrm{I}_{2}(\mathrm{v})\right)-\sigma \mathrm{W}^{\#}(\mathrm{v}) \vee \sigma \mathrm{U}_{-}(\overline{\mathrm{W}}(\mathrm{v}))\right| \geq \mathrm{a} \sqrt{\mathrm{v}}\right) \leq 4 \varepsilon \tag{11.5}
\end{equation*}
$$

According to (4.7) and (4.11), on $E_{7} \cap E_{9}$,

$$
\log \left(I_{1}(v) \vee I_{2}(v)\right) \leq\left(\sigma W^{\#}(v)+\log ^{4} v\right) \vee \sigma U_{-}\left(\bar{W}(v)+\log ^{4} v\right)
$$

Let $E_{26}=\left\{U_{-}\left(\bar{W}(v)+\log ^{4} v\right) \leq U_{-}(\bar{W}(v))+v^{1 / 3}\right\}$ as defined. Then $\mathbb{P}\left(E_{26}^{c}\right)$ $\leq \mathbb{P}\left(U_{-}\left(\log ^{4} v\right) \geq v^{1 / 3}\right)=\left(\log ^{4} v\right) / v^{1 / 3}<\varepsilon$, for large $v$. On the other hand, it follows from Lemmas 4.1 and 4.2 that $\mathbb{P}\left(\mathrm{E}_{7}^{\mathrm{c}} \cup \mathrm{E}_{9}^{\mathrm{c}}\right) \leq\left(\mathrm{C}_{9}+\mathrm{C}_{10}\right) \exp \left(-\log ^{2} \mathrm{v}\right)$ $<\varepsilon$. Now, on $\mathrm{E}_{7} \cap \mathrm{E}_{9} \cap \mathrm{E}_{26}$,

$$
\begin{aligned}
\log \left(\mathrm{I}_{1}(\mathrm{v}) \vee \mathrm{I}_{2}(\mathrm{v})\right) & \leq \sigma \mathrm{v}^{1 / 3}+\sigma \mathrm{W}^{\#}(\mathrm{v}) \vee \sigma \mathrm{U}_{-}(\overline{\mathrm{W}}(\mathrm{v})) \\
& <\mathrm{a} \sqrt{\mathrm{v}}+\sigma \mathrm{W}^{\#}(\mathrm{v}) \vee \sigma \mathrm{U}_{-}(\overline{\mathrm{W}}(\mathrm{v}))
\end{aligned}
$$

Consequently, for all sufficiently large v,
(11.6) $\mathbb{P}\left[\log \left(\mathrm{I}_{1}(\mathrm{v}) \vee \mathrm{I}_{2}(\mathrm{v})\right) \geq \mathrm{a} \sqrt{\mathrm{v}}+\sigma \mathrm{W}^{\#}(\mathrm{v}) \vee \sigma \mathrm{U}_{-}(\overline{\mathrm{W}}(\mathrm{v}))\right]<2 \varepsilon$.

A similar argument based again on Lemmas 4.1 and 4.2 leads to the following lower bound for $\log \left(I_{1}(v) \vee I_{2}(v)\right)$ :

$$
\begin{equation*}
\mathbb{P}\left[\log \left(\mathrm{I}_{1}(\mathrm{v}) \vee \mathrm{I}_{2}(\mathrm{v})\right) \leq-\mathrm{a} \sqrt{\mathrm{v}}+\sigma \mathrm{W}^{\#}(\mathrm{v}) \vee \sigma \mathrm{U}_{-}(\overline{\mathrm{W}}(\mathrm{v}))\right] \leq 2 \varepsilon \tag{11.7}
\end{equation*}
$$

Combining (11.6) with (11.7) yields (11.5), hence Proposition 11.1.

Acknowledgments. We are grateful to Marc Yor for stimulating discussions and insightful comments and to Pierre Mathieu for hel pful references. Many thanks are due to an anonymous referee for careful reading of the original manuscript and for invaluable suggestions.
