# On negative-definite cobordisms among lens spaces of type $(m, 1)$ and uniformization of four-orbifolds 

Yoshihiro Fukumoto

#### Abstract

Connected sums of lens spaces which smoothly bound a rational homology ball are classified by P Lisca. In the classification, there is a phenomenon that a connected sum of a pair of lens spaces $L(a, b) \# L(a,-b)$ appears in one of the typical cases of rational homology cobordisms. We consider smooth negative-definite cobordisms among several disjoint union of lens spaces and a rational homology 3 -sphere to give a topological condition for the cobordism to admit the above "pairing" phenomenon. By using Donaldson theory, we show that if $1 / m$ has a certain minimality condition concerning the Chern-Simons invariants of the boundary components, then any $L(m, 1)$ must have a counterpart $L(m,-1)$ in negative-definite cobordisms with a certain condition only on homology. In addition, we show an existence of a reducible flat connection through which the pair is related over the cobordism. As an application, we give a sufficient condition for a closed smooth negative-definite 4 -orbifold with two isolated singular points whose neighborhoods are homeomorphic to the cones over lens spaces $L(m, 1)$ and $L(m,-1)$ to admit a finite uniformization.

## 1 Introduction

Lisca [25] classified all connected sums of lens spaces which smoothly bound rational homology 4-balls. In fact, all of them are connected sums of several pairs of lens spaces in the list of five typical families of components such as $L(a, b) \# L(a,-b)$ for coprime $a$ and $b$. In particular, if a connected sum of $s$ copies of $L(m, 1)$ and $t$ copies of $L(m,-1)$ bounds a rational homology ball then $s$ must be equal to $t$. In this classification, a crucial role was played by Donaldson's theorem on intersection forms of definite closed smooth 4-manifolds. Motivated by this result, we focus on the formation of pairs $L(a, b) \# L(a,-b)$ on the boundaries of compact oriented smooth 4 -manifolds $W$ such that the dimension $b_{2}^{+}(W)$ of a maximal positive subspace for the cup product (intersection form) on the second real cohomology $H^{2}(W)$ of $W$ is zero, called negative-definite cobordisms.

To be precise, we consider the following problem:
Problem 1.1 Which negative-definite cobordisms between a disjoint union of lens spaces and a rational homology 3 -sphere admit a pair of lens spaces $L(a, b) \# L(a,-b)$ ?

In this paper, we show the following theorem:
Theorem 1.2 Let $Y$ be a disjoint union of lens spaces $Y_{i}=L\left(a_{i}, b_{i}\right)$ for $i=1, \ldots, s$ and a Brieskorn homology 3 -sphere $\Sigma(p, q, r)$. Suppose $Y$ bounds a compact oriented negative-definite smooth 4-manifold $W$ such that
(1) $Y_{1}=L(m, 1)$ with $m=\max \left\{a_{i}\right\}>p q r$ and $m \neq 4$,
(2) the homomorphism

$$
i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(W ; \mathbb{Z})
$$

induced by the inclusion $i: Y \hookrightarrow W$ is surjective, and
(3) there is no $e \in H^{2}(W ; \mathbb{Z})$ with rational self-intersection number $e^{2}=-1 / m$.

Then there exists $i \neq 1$ such that $Y_{i}=L(m,-1)$.
Note that this theorem does not exclude the possibility $s=1$, in which case we immediately see such a cobordism $W$ does not exist and $s>1$ must hold. Here we remark that this Theorem 1.2 is a special case of our main Theorem 4.1, which is a generalization of Theorem 2.1 in [16] and Theorem 6.1 in [14], both due to M Furuta. To prove our main result, we make use of a topology of the moduli space of $\mathrm{SU}(2)$ instantons on an oriented smooth 4 -manifold with cylindrical ends.

Remark 1.3 (1) The condition $m \neq 4$ in Theorem 1.2 is necessary. In fact, without this condition, the complement $W$ of a tubular neighborhood of a non-singular quadratic curve in $\overline{\mathbb{C} P^{2}}$ would give a counterexample.
(2) The existence of an $L(m,-1)$ does not necessarily imply the existence of an $L(m, 1)$ in negative-definite cobordisms stated in Theorem 1.2 , since $L(3,-1)$ obtained by plumbing of linear chain $[-2,-2]$ of length 2 with weight -2 would give a counterexample.

Our main result, Theorem 4.1, and Theorem 6.1 in [14] also state existence of a reducible flat connection on such negative-definite cobordisms as in Theorem 1.2. As an application we consider a uniformization problem of 4 -orbifolds. The notion of orbifolds is firstly introduced by I Satake [30] as the name " $V$-manifold" in his study
on Siegel's modular varieties and is also studied by W Thurston [33] as orbifolds in view of his geometrization program on 3-manifolds. A typical example is a quotient space $X=M / G$ of a manifold $M$ with respect to a properly discontinuous action of a (finite) group $G$, in which case $M$ is called a (finite) uniformization of the orbifold $X$. Note that there exist orbifolds which do not admit uniformization; these are called "bad orbifolds".

In this paper, we consider a version of the "uniformization problem" proposed by M Kato [20] in our context. In the complex analytic category, this problem also has its origin in "Fenchel's problem" raised by M Namba [26] as a higher-dimensional generalization of Fenchel's conjecture about $F$-groups, solved by S Bundgaard and J Nielsen [5] and R Fox [13].

Problem 1.4 (see the uniformization problem [20]) Let $X$ be a smooth orbifold with singular locus $\Sigma X$. Give a good condition on $(X, \Sigma X)$ for the existence of a finite uniformization ( $G, M$ ) of $(X, \Sigma)$.

Here a "good" condition means a condition without referring to the fundamental group $\pi_{1}(X-\Sigma X)$ of $X-\Sigma X$.

For a $\mathbb{Z}_{m}$-action on the 4 -sphere $S^{4}=\mathbb{C}^{2} \cup\{\infty\}$ defined by $\zeta \cdot(z, w)=\left(\zeta z, \zeta^{-1} w\right)$ on $\mathbb{C}^{2} \subset S^{4}$ for $\zeta=e^{2 \pi i / m} \in \mathbb{Z}_{m} \subset U(1)$, the quotient space $X=S^{4} / \mathbb{Z}_{m}$ is a 4-dimensional orbifold which has a singular point $p_{1}=0$ whose neighborhood $U_{1}$ is homeomorphic to the cone $c L(m,-1)$ over the lens space $L(m,-1)$, and there is also a singular point $p_{2}=\infty$ whose neighborhood $U_{2}$ is homeomorphic to the cone $c L(m, 1)$ over the lens space $L(m, 1)$. Conversely, we have the following:

Theorem 1.5 Let $X$ be a closed negative-definite smooth 4-orbifold with two isolated singular points $p_{1}$ and $p_{2}$, each with a neighborhood $U_{i}$ homeomorphic to the cone $c L\left(a_{i}, b_{i}\right)$ over the lens space $L\left(a_{i}, b_{i}\right)$ for $i=1,2$. Suppose $H_{1}(X ; \mathbb{Z})=\{0\}$ and that there is no $e \in H^{2}(X ; \mathbb{Z})$ with $e^{2}=-1 / m$ for $m=\max \left\{a_{1}, a_{2}\right\} \neq 4$. If $U_{1} \approx c L(m,-1)$ then $U_{2} \approx c L(m, 1)$ and there exists a smooth 4-manifold $\tilde{X}$ with a smooth $\mathbb{Z}_{m}$-action such that $\tilde{X} / \mathbb{Z}_{m} \cong X$ as smooth orbifolds.

This paper is organized as follows. In Section 2, we make further remarks on our main result, Theorem 4.1, and its backgrounds in comparison with other works. In Section 3, we recall basic definitions and results concerning the moduli space of instantons over 4 -manifolds with cylindrical ends. Here we give a setting of moduli space of instantons and recall basic facts on counting reducible instantons, virtual dimension of the moduli
space, Uhlenbeck compactness and Chern-Simons invariants. In particular, to describe the ends of the moduli space, we discuss the moduli space of $\mathbb{Z}_{m}$-invariant instantons over the cylinder $\mathbb{R} \times S^{3}$, C Taubes' gluing result and discuss a holonomy perturbation to deform the ends of the moduli space. In Section 4, we give the full statement of our main result, Theorem 4.1, and give a proof of the theorem. We also discuss several examples to demonstrate necessity of the conditions in the theorem. In Section 5, we prove Theorem 1.5 on a cyclic branched covering of a negative-definite smooth 4 -orbifold. In fact, we deduce Theorem 5.1 as a corollary of Theorem 4.1, which gives a cyclic branched covering of a smooth negative-definite 4 -orbifold with boundary and with isolated singular points whose neighborhoods are homeomorphic to the cones over lens spaces $L\left(a_{i}, b_{i}\right)$. The branched covering space is an orbifold itself which locally uniformizes only a pair of neighborhoods homeomorphic to the cones over lens spaces $L(m, 1)$ and $L(m,-1)$.

Acknowledgements The author thanks Professor Mikio Furuta for many valuable suggestions and continual encouragement to write down this paper. He would also like to thank to Nobuhiro Nakamura, Hirofumi Sasahira and Shinichiroh Matsuo for detailed discussions and valuable comments. The author was a visiting scholar of the Department of Mathematics at Indiana University Bloomington while most of this work was carried out. He wishes to thank the department for its hospitality and would like to thank his hosts, Professor Paul Kirk and Professor Charles Livingston, for illuminating discussions, many suggestive comments and much encouragement during his stay.

## 2 Further remarks on the main theorem and background

In this section, we make further remarks on the main theorem and its background. In addition to Problem 1.1, the main theorem partially answers the following problem:

Problem 2.1 If there exists a negative-definite cobordism between a disjoint union $Y$ of several lens spaces $L\left(a_{i}, b_{i}\right)$ and a rational homology sphere $\Sigma$, what kind of constraint for the homomorphism $i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(W ; \mathbb{Z})$ induced by the inclusion $i: Y \hookrightarrow W$ can be expected ?

Theorem 4.1 tells us that the pair $L(m, 1) \# L(m,-1)$ is related through a $U(1)$ flat connection on the cobordism $W$, which implies the existence of a homomorphism $H_{1}(W ; \mathbb{Z}) \rightarrow U(1)$ whose restrictions are the standard inclusion up to complex conjugation on $L(m, \pm 1)$ and trivial on the other components of the boundary.

One typical example is the plumbed homology 3 -sphere $\Sigma=\Sigma(\Gamma)$ associated to a graph $\Gamma$ by taking the connected sum $W=([0,1] \times L(m, 1)) \# P(\Gamma)$ of the cylinder $[0,1] \times L(m, 1)$ and the plumbing $P(\Gamma)$ with negative-definite intersection form. In this case, the homomorphism $\chi: H_{1}(W ; \mathbb{Z})=H_{1}(L(m, 1) ; \mathbb{Z}) \rightarrow U(1)$ is given by the inclusion $\mathbb{Z}_{m} \hookrightarrow U(1)$.

In [14], Furuta developed an abstract perturbation method to prove Donaldson's theorem for intersection forms on closed smooth definite 4 -manifolds $X$ with $H_{1}(X ; \mathbb{Z})=\{0\}$. As an application, he strengthened Theorem 2.1 of [16], which made an assumption on the fundamental group of the 4 -manifold (orbifold), to prove Theorem 6.1 of [14], which only makes an assumption on the first homology and proved an existence of an abelian representation. One major difference between our Theorem 4.1 and [14, Theorem 6.1] is that our theorem allows for a general rational homology 3 -spheres as components of $Y$ which are not necessarily spherical space forms. One consequence of this is that we cannot apply Theorem 2.1 of [16] to prove our theorem by simply coning off the boundary components to obtain closed orbifold.

Theorem 4.1 states that even if there is another rational homology 3 -sphere $\Sigma$ on the boundary, the pair $L(m, 1) \# L(m,-1)$ appears provided $m$ is greater than a positive number $N(\Sigma)$ associated to $\Sigma$. In fact, we may choose any number $N(\Sigma)$ in the statement of Theorem 4.1 such that $1 / N(\Sigma)$ is less than or equal to the minimum Chern-Simons invariant $\tau(\Sigma)$ of $\Sigma$, and if $\Sigma$ is the Brieskorn homology 3-sphere $\Sigma(p, q, r)$ then we can take $N(\Sigma)=p q r$ [15; 12]. By using a method developed by P Kirk and E Klassen [22], the Chern-Simons invariant can be calculated for many 3 -manifolds including graph manifolds. In fact, the Chern-Simons invariants of a large class of manifolds including Seifert fibered 3-manifolds are explicitly calculated by D Auckly [4]. Here we mention the following remarks:

Remark 2.2 (1) Theorem 4.1 does not tell us whether $\chi \circ\left(i_{j}\right)_{*}$ for $j \in\{1, i\}$ is the inclusion $\rho$ : $\mathbb{Z}_{m} \hookrightarrow U(1)$ or its complex conjugate. We shall discuss this issue and uniformization of 4 -orbifolds with more than two isolated singular points elsewhere.
(2) The condition $m>N(\Sigma)$ cannot be removed. In fact, the singular $D^{2}$-bundle $\widehat{W}=\Sigma \times_{S^{1}} D^{2}$ associated with the Seifert fibration $\Sigma \rightarrow S^{2}$ of negative rational Euler number with the cone over lens spaces removed would give a counterexample.
(3) Theorem 1.2 is a special case of the main result, Theorem 4.1, in which we treat the case that the boundary components are not necessarily lens spaces but "positive" (or "negative") spherical space forms. In this case we obtain a not necessarily reducible flat connection relating the pair of positive and negative spherical space forms.
(4) Theorems 1.2 and 4.1 can be extended to the case of lens spaces $L(a, b)$ with $a$ sufficiently greater than $b$ in place of $L(m, 1)$. We shall treat this elsewhere.

To prove an existence of a (reducible) flat connection over an oriented smooth 4manifold with cylindrical ends under a certain condition on homology, we make use of the "sliding end" or "bubbling" phenomenon of SU(2)-instantons. The author does not know how to deduce our theorem from usual applications of the Seiberg-Witten theory or Heegaard Floer theory since we do not know how to extract information on flat $\mathrm{SU}(2)$ connections in these theories at least as directly as in the Donaldson theory.

There are several areas in which the Donaldson theory works effectively while the Heegaard Floer theory or Seiberg-Witten theory alone would be difficult to approach. It is known that the Seifert fibered integral homology 3 -spheres $\Sigma(p, q, p q k-1)$ for $k=1,2, \ldots$ are linearly independent in the homology cobordism group $\theta_{3}^{H}$ of homology 3 -spheres by a result of Furuta [15] and R Fintushel and R Stern [12]. For the $\mathbb{Z} / 2-$ homology cobordism group, M Hedden and Kirk [18] showed that $d /\left(d^{k}-1\right)$ surgeries on the right-handed $(p, q)$ torus knot are linearly independent. Hedden and Kirk [19] also showed that the Whitehead doubles of $\left(2,2^{n}-1\right)$ torus knots are independent in the smooth knot concordance group. This result is generalized by J Pinzón-Caicedo [27] to infinite collections of satellite knots. Note that positivity of the $R$-invariant introduced by Fintushel and Stern in [10] as the virtual dimension of the moduli space of instantons plays a crucial role in these arguments. On Ozsváth and Szabó's Heegaard Floer theory, S Kim and C Livingston [21] proved that $\mathbb{Z}^{\infty} \subset \operatorname{Coker}\left(\bigoplus_{p} \theta_{\mathbb{Z}[1 / p]}^{3} \rightarrow \theta_{\mathbb{Q}}^{3}\right)$ by using the $d$-invariant. Recently, M Stoffregen [32] investigated behaviors of Manolescu invariants $\alpha, \beta, \gamma$ on Seiberg-Witten Floer homology under connected sums and used also recent result on Heegaard Floer homology to show that $\Sigma(p, 2 p-1,2 p+1)$ for odd $p$ with $p \geq 3$ are linearly independent in $\theta_{3}^{H}$. However, this technique does not detect the family $\Sigma(p, q, p q k-1)$.

Our result is in a sense opposite to that of A Casson and C Gordon [6], P Gilmer and Livingston [17] and Fintushel and Stern [11]. In fact, their arguments give a necessary condition for characters $\chi_{i}: H_{1}\left(Y_{i} ; \mathbb{Z}\right) \rightarrow \mathbb{Z}_{m} \subset U(1)$ of spherical space forms $Y_{i}$ to
extend over a rational homology cobordism $W$, which implies a necessary condition for an existence of a $\mathbb{Z}_{m}$-covering $\widetilde{W} \rightarrow W$ extending the $\mathbb{Z}_{m}$-coverings $\widetilde{Y}_{i} \rightarrow Y_{i}$ associated to the character $\rho_{i}$. On the other hand, our result gives a sufficient condition for $Y_{i}$ and their negative-definite cobordism $W$ with a character $\chi_{1}: H_{1}\left(Y_{1} ; \mathbb{Z}\right) \rightarrow$ $\mathbb{Z}_{m} \subset U(1)$ to extend over $H_{1}(W ; \mathbb{Z})$, which implies a sufficient condition for the existence of $\mathbb{Z}_{m}$-covering $\widetilde{W} \rightarrow W$ extending $\widetilde{Y}_{1} \rightarrow Y_{1}$.

In the Casson-Gordon argument, D Ruberman [28] extended their result for spherical space forms to rational space forms, that is, rational homology 3 -spheres divided by finite group actions, using the moduli space of instantons on 4 -manifolds with cylindrical ends. To extend our result for lens spaces to one for general rational homology 3 -spheres such as rational space forms, we need to know the moduli space on the cylinder over rational space forms which corresponds to the end of the moduli space. This deserves further study.

For a simply connected smooth 4 -manifold $X_{0}$ with boundary the Poincaré homology 3-sphere $\Sigma(2,3,5)$ and negative-definite intersection form $Q_{X_{0}}=E_{8}$, N Anvari [2] gave a necessary condition for a free $\mathbb{Z}_{p}$-action on $\Sigma(2,3,5)$ to extend smoothly to $X_{0}$ by using the isotropy data of isolated fixed points. This result is proved by considering the $\mathbb{Z}_{p}$-equivariant moduli space of instantons over the 4 -manifold with a cylindrical end. Furthermore, Anvari and I Hambleton [3] gave infinite families of Brieskorn homology 3 -spheres with free $\mathbb{Z}_{p}$-actions which can be extended locally linearly but cannot smoothly to smooth contractible 4 -manifolds. To study relationships with their results, we will consider a negative-definite cobordism between the quotient $\Sigma\left(a_{1}, \ldots, a_{n}\right) / \mathbb{Z}_{p}$ and a disjoint union of lens spaces.

H Sasahira [29] defined Floer homology for lens spaces by treating problems on reducible connections via Furuta's method using twisted Dirac operators and derived a gluing formula by Fukaya's method using loops. To give an interpretation of our arguments in terms of Floer homology for lens spaces will be a subject of our future work.

## 3 Preliminaries on instantons over 4-manifolds with cylindrical ends

In this section, we recall basic definitions and results on analysis concerning instantons over 4-manifolds with cylindrical ends. We discuss a new feature which was not treated in [16], a perturbation of the moduli space called holonomy perturbation introduced by Donaldson [7], which we use to prove a key theorem, discussed in Section 4.

### 3.1 Instantons over 4-manifolds with cylindrical ends

Let $Y$ be a disjoint union of a finite number of closed oriented 3-manifolds $Y_{i}$ indexed by $i \in I$ and $W$ be a compact oriented smooth 4-manifold with boundary $Y$. Let $X$ be a smooth oriented 4 -manifold obtained by gluing $W$ and half-infinite cylinders $\mathbb{R}_{+} \times Y_{i}$ with product orientation along the boundaries $\{0\} \times Y_{i}$, where $\mathbb{R}_{+}=\{t \in \mathbb{R} \mid t \geq 0\}$. In what follows we simply describe such a manifold $X$ as a " 4 -manifold with cylindrical ends". Let ( $P, \alpha$ ) be an adapted $\mathrm{SU}(2)$-bundle over $X$, that is, a pair of a principal $\mathrm{SU}(2)$-bundle $P$ over $X$ and a set $\alpha=\left\{\alpha_{i}\right\}$ of flat $\mathrm{SU}(2)-$ connections $\alpha_{i}$ on $\left.P\right|_{\mathbb{R}_{+} \times Y_{i}}$. We may assume that $\alpha_{i}$ is a pullback $p_{i}^{*} \beta_{i}$ by the projection $p_{i}: \mathbb{R}_{+} \times Y_{i} \rightarrow Y_{i}$ of a flat connection $\beta_{i}$ on an $\operatorname{SU}(2)$-bundle $Q_{i}$ over $Y_{i}$ under an identification $\left.P\right|_{\mathbb{R}_{+} \times Y_{i}} \cong p_{i}^{*} Q_{i}$ using parallel transport in the direction $\mathbb{R}_{+}$ with respect to the connection $\alpha_{i}$. We do not distinguish $\alpha_{i}$ and $\beta_{i}$ in the sequel. Two adapted bundles $(P, \alpha)$ and $\left(P^{\prime}, \alpha^{\prime}\right)$ are equivalent if and only if there exists a bundle isomorphism $h: P \rightarrow P^{\prime}$ such that $\left.\alpha_{i}\right|_{[r, \infty) \times Y_{i}}=\left.h^{*} \alpha_{i}^{\prime}\right|_{[r, \infty) \times Y_{i}}$ for some $r>0$ for any $i \in I$. Let $\theta$ be the trivial flat connection (the product connection) on the product bundle $X \times \mathrm{SU}(2) \rightarrow X$. Then the trivial flat connection $\theta_{i}$ on the restriction $\left.(X \times \mathrm{SU}(2))\right|_{\mathbb{R}_{+} \times Y_{i}}$ over each ends $\mathbb{R}_{+} \times Y_{i} \subset X$ is induced by $\theta$ and we call the adapted bundle isomorphic to $\left(X \times \mathrm{SU}(2),\left\{\theta_{i}\right\}\right)$ the trivial adapted bundle. The second Chern number of $(P, \alpha)$ is defined to be

$$
c_{2}(P, \alpha)=\frac{1}{8 \pi^{2}} \int_{X} \operatorname{Tr}\left(F_{A} \wedge F_{A}\right),
$$

where $A$ is a smooth connection on $P$ with $\left.A\right|_{[r, \infty) \times Y_{i}}=\left.\alpha_{i}\right|_{[r, \infty) \times Y_{i}}$ for some $r>0$ for any $i \in I$, and it does not depend on a choice of such connections $A$. If we fix $\mathrm{SU}(2)$-bundles $Q_{i}$ over $Y_{i}$ and flat connections $\beta_{i}$ on $Q_{i}$, then the isomorphism classes of adapted bundles $(P, \alpha)$ with a bundle isomorphism $h_{i}:\left.P\right|_{\mathbb{R}_{+} \times Y_{i}} \cong p_{i}^{*} Q_{i}$ satisfying $\alpha_{i}=h_{i}^{*} \beta_{i}$ are classified by $c_{2}(P, \alpha)$ and if $\left(P^{\prime}, \alpha\right)$ is another such bundle then $c_{2}\left(P^{\prime}, \alpha\right)-c_{2}(P, \alpha) \in \mathbb{Z}$.

Now we identify the gauge equivalence classes of the flat connection $\alpha_{i}$ with the conjugacy classes of representation of $\pi_{1}\left(Y_{i}\right)$ induced by the holonomy of $\alpha_{i}$ and use the same symbol $\alpha_{i}$. Let ad $\alpha_{i}$ be the adjoint representation of $\alpha_{i}$ and place the non-degeneracy condition $H^{1}\left(Y_{i} ; \operatorname{ad} \alpha_{i}\right)=\{0\}$ on each flat connection $\alpha_{i}$. Note that if $Y_{i}$ is a spherical space form $S^{3} / G$ for some finite group $G$ acting on $S^{3}$ with a flat connection $\alpha_{i}$ corresponding to a representation $\rho: G \rightarrow \mathrm{SU}(2)$, then $H^{1}\left(S^{3} / G ; \operatorname{ad} \rho\right)=$ $\left(H^{1}\left(S^{3} ; \mathbb{R}\right) \otimes \mathfrak{s u}(2)\right)^{\text {ad } \rho}=\{0\}$, and that if $Y_{i}$ is a rational homology 3-sphere $\Sigma$ and
$\alpha_{i}$ is a trivial flat connection $\theta$, then $H^{1}(\Sigma ; \operatorname{ad} \theta)=H^{1}(\Sigma ; \mathbb{R}) \otimes \mathfrak{s u}(2)=\{0\}$, so they satisfy the non-degeneracy condition.

Fix a Riemannian metric $g_{i}$ on each $Y_{i}$ and choose a metric $g$ on $X$ which matches the product metrics over ends $\left.g\right|_{\mathbb{R}_{+} \times Y_{i}}=d t^{2}+g_{i}$. Let $D_{A}$ be the deformation operator associated to a connection $A$ on $P$ which restricts to $\alpha_{i}$ on $[r, \infty) \times Y_{i}$ for each $i$ for some $r>0$,

$$
D_{A}=-d_{A}^{*} \oplus d_{A}^{+}: \Omega^{1}\left(\mathfrak{g}_{P}\right) \rightarrow \Omega^{0}\left(\mathfrak{g}_{P}\right) \oplus \Omega_{+}^{2}\left(\mathfrak{g}_{P}\right)
$$

and let $L_{\alpha_{i}}$ be the selfadjoint elliptic operator over $Y_{i}$ such that

$$
D_{A}=\frac{d}{d t}+L_{\alpha_{i}}
$$

over $[r, \infty) \times Y_{i}$. Let $\delta>0$ be a positive real number less than the absolute values of the eigenvalues of the selfadjoint operator $L_{\alpha_{i}}$ for any $i \in I$. Fix a smooth function $w: X \rightarrow \mathbb{R}$ satisfying $w \geq \frac{1}{2}$ over $X$ and $w(t, y)=e^{\delta t}$ on each end $(t, y) \in \mathbb{R}_{+} \times Y_{i}$ and define a weighted Sobolev norm $\|\phi\|_{L_{k}^{2, \delta}}=\|w \phi\|_{L_{k}^{2}}$ for an integer $k \geq 0$. Fix an integer $l>2$. Take a reference smooth connection $A_{0}$ on $P$ with $\left.A_{0}\right|_{\mathbb{R}_{+} \times Y_{i}}=\alpha_{i}$. Let $\mathcal{A}(P, \alpha)$ be the space of $L_{l}^{2, \delta}$-connections on $P$ and $\mathcal{G}(P, \alpha)$ be the group of $L_{l+1, \text { loc }}^{2, \delta}$-gauge transformations on $P$ defined as follows:

$$
\begin{aligned}
& \mathcal{A}(P, \alpha)=\left\{A_{0}+a \mid a \in L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P}\right)\right)\right\} \\
& \mathcal{G}(P, \alpha)=\left\{g \in \Gamma\left(P \times_{\mathrm{Ad}} G\right) \mid \nabla_{A_{0}} g \in L_{l}^{2, \delta}\left(\bigwedge^{1}\left(P \times_{\mathrm{Ad}} G\right)\right)\right\}
\end{aligned}
$$

Then $\mathcal{G}(P, \alpha)$ is a Hilbert Lie group acting smoothly on the Hilbert manifold $\mathcal{A}(P, \alpha)$ by $g \cdot A=A-d_{A} g \cdot g^{-1}$ for $A \in \mathcal{A}(P, \alpha), g \in \mathcal{G}(P, \alpha)$ to define the quotient topological space $\mathcal{B}(P, \alpha)=\mathcal{A}(P, \alpha) / \mathcal{G}(P, \alpha)$. Now the condition that $\nabla_{A_{0}} g \in L_{l}^{2, \delta}$ with weighted norm forces any gauge transformation $g \in \mathcal{G}(P, \alpha)$ to have a uniform limit along each cylinder $\mathbb{R}_{+} \times Y_{i}$. Let ev: $\mathcal{G}(P, \alpha) \rightarrow \Gamma_{\alpha}$ be the evaluation homomorphism to the stabilizer $\Gamma_{\alpha}=\prod_{i \in I} \Gamma_{\alpha_{i}}$ of $\alpha$ and define the based gauge group $\mathcal{G}_{0}(P, \alpha)$ to be the kernel of the map ev. Then $\mathcal{G}_{0}(P, \alpha)$ acts on $\mathcal{A}(P, \alpha)$ freely and the quotient

$$
\tilde{\mathcal{B}}(P, \alpha)=\mathcal{A}(P, \alpha) / \mathcal{G}_{0}(P, \alpha)
$$

is a Hilbert manifold with local model

$$
T_{[A]} \widetilde{\mathcal{B}}(P, \alpha)=\left\{A+a \mid a \in L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P}\right)\right), d_{A}^{*, \delta} a=0\right\}
$$

where $d_{A}^{*, \delta}=w^{-2} \cdot d_{A}^{*} \cdot w^{2}$. The full quotient $\mathcal{B}(P, \alpha)$ is obtained by dividing $\widetilde{\mathcal{B}}(P, \alpha)$ with the extra symmetry $\mathcal{G}(P, \alpha) / \mathcal{G}_{0}(P, \alpha) \cong \Gamma_{\alpha}$,

$$
p: \widetilde{\mathcal{B}}(P, \alpha) \rightarrow \widetilde{\mathcal{B}}(P, \alpha) / \Gamma_{\alpha}=\mathcal{B}(P, \alpha) .
$$

A connection $A$ is called an anti-self-dual (ASD) connection or simply an "instanton" if and only if the curvature $F_{A}$ is anti-self-dual, $F_{A}^{+}=\frac{1}{2}\left(F_{A}+\star F_{A}\right)=0$, where $\star$ is the Hodge star operator with respect to the metric $g$. Then we have a $\mathcal{G}(P, \alpha)$-equivariant smooth map

$$
\Phi: \mathcal{A}(P, \alpha) \rightarrow L_{l-1}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right), \quad \Phi(A)=F_{A}^{+} \quad \text { for } A \in \mathcal{A}(P, \alpha)
$$

Let $\mathcal{M}(P, \alpha)$ be the moduli space of instantons on $(P, \alpha)$,

$$
\mathcal{M}(P, \alpha)=\left\{A \in \mathcal{A}(P, \alpha) \mid F_{A}^{+}=0\right\} / \mathcal{G}(P, \alpha),
$$

which can be seen as the quotient of the framed moduli space $\tilde{\mathcal{M}}(P, \alpha)=p^{-1}(\mathcal{M}(P, \alpha))$ divided by the free $\Gamma_{\alpha}$-action. By non-degeneracy condition $H^{1}\left(Y_{i} ; \operatorname{ad} \alpha_{i}\right)=\{0\}$, any instanton $A$ over $(P, \alpha)$ decays exponentially to the flat connection $\alpha_{i}$ up to gauge transformation toward the ends $\mathbb{R}_{+} \times Y_{i}$. In particular, for any connection $B$ which is equal to $\alpha_{i}$ over ends, since $\left|F_{A}\right|$ decays exponentially along ends, $\left\|F_{A}\right\|_{L^{2}(X)}^{2}=$ $\int_{X}\left|F_{A}\right|^{2} \operatorname{vol}_{X}=\int_{X}\left|F_{B}\right|^{2} \operatorname{vol}_{X}=8 \pi^{2} c_{2}(P, \alpha)$.

### 3.2 Enumeration of reducible instantons for $\mathbf{S U}(2)$

If a connection $A$ on the adapted $\mathrm{SU}(2)$-bundle $(P, \alpha)$ has the isotropy subgroup $\mathcal{G}(P, \alpha)_{A}$ of the gauge group $\mathcal{G}(P, \alpha)$ isomorphic to $\{ \pm 1\}$ then $A$ is said to be $i r-$ reducible; otherwise, $A$ is reducible. In particular, reducible instantons, which are reducible connections on ( $P, \alpha$ ) whose curvature 2 -forms are anti-self-dual, correspond to the singular points of the moduli space $\mathcal{M}(P, \alpha)$.

For later discussion, we need to count reducible instantons for adapted $\mathrm{SU}(2)$-bundles over 4 -manifolds with cylindrical ends. Hedden and Kirk [18] described enumeration of reducible instantons in the case that the gauge group is $\mathrm{SO}(3)$.

Proposition 3.1 Let $(P, \alpha)$ be an adapted $\mathrm{SU}(2)$-bundle over a 4 -manifold $X$ with cylindrical ends $\mathbb{R}_{+} \times Y_{j}$ for $j \in I$, where $Y_{j}$ are rational homology 3-spheres. Suppose that the $\mathrm{SU}(2)$ flat connections $\alpha_{j}$ are all reducible, so that the corresponding representation $\alpha_{j}: \pi_{1}\left(Y_{j}\right) \rightarrow U(1)$ is determined up to complex conjugation. Then
there exists a one-to-one correspondence between the set of all reducible instantons $\mathcal{M}_{\text {red }}(P, \alpha) \subset \mathcal{M}(P, \alpha)$ on $(P, \alpha)$ and the set

$$
C(P, \alpha)=\left\{e \in H^{2}(X ; \mathbb{Z}) \mid e^{2}=-c_{2}(P, \alpha), i_{j}^{*} e= \pm e\left(L_{j}\right) \text { for } j \in I\right\} /\{ \pm 1\}
$$

where $i_{j}: Y_{j} \hookrightarrow X$ is the inclusion and $L_{j}$ is the flat $S^{1}$-bundle over $Y_{j}$ associated with $\alpha_{j}$. Note that $e\left(L_{j}\right)$ is determined up to sign because the representation $\alpha_{j}: \pi_{1}\left(Y_{j}\right) \rightarrow U(1)$ is determined up to complex conjugation.

Proof The proof goes essentially the same as in the $\mathrm{SO}(3)$ case discussed by Hedden and Kirk [18]. In our $\operatorname{SU}(2)$ case, the primary obstruction of extending gauge transformations from the boundary $Y$ to $X$ gives an element of $H^{2}\left(X, Y ; \pi_{1}(\mathrm{SU}(2))\right)=\{0\}$.

### 3.3 Perturbation on a compact part of the moduli space

In this subsection, we state the following proposition, used in the discussion below. Let $X$ be a smooth oriented 4 -manifold with cylindrical ends and $(P, \alpha)$ be an adapted $\mathrm{SU}(2)$-bundle over $X$. Fix a Riemannian metric on $X$ with product ends.

Let $l$ be an integer satisfying $l>2$ and consider the space $\mathcal{B}(P, \alpha)$ of the gauge equivalence classes of $L_{l}^{2, \delta}$-connections on $(P, \alpha)$. We let $\mathcal{B}^{*}(P, \alpha)$ be the irreducible part of $\mathcal{B}(P, \alpha)$,

$$
\mathcal{B}^{*}(P, \alpha)=\mathcal{A}^{*}(P, \alpha) / \mathcal{G}(P, \alpha), \quad \mathcal{A}^{*}(P, \alpha)=\left\{A \in \mathcal{A}(P, \alpha) \mid \mathcal{G}(P, \alpha)_{A}=\{ \pm 1\}\right\}
$$

and let $\widetilde{\mathcal{B}}^{*}(P, \alpha)=p^{-1}\left(\mathcal{B}^{*}(P, \alpha)\right)$, where $\mathcal{G}(P, \alpha)_{A}$ is the stabilizer of $A$ in $\mathcal{G}(P, \alpha)$.
Let $\tau$ be a $\mathcal{G}(P, \alpha)$-equivariant smooth map $\mathcal{A}(P, \alpha) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)$ followed by compact embedding $L_{l}^{2, \delta} \subset L_{l-1}^{2, \delta}$, and consider the $\mathcal{G}(P, \alpha)$-equivariant map defined by the formula

$$
\Phi_{\tau}(A)=F_{A}^{+}+\tau(A) \quad \text { for } A \in \mathcal{A}(P, \alpha)
$$

Its derivative

$$
d_{A}^{+}+(D \tau)_{A}: \operatorname{Ker} d_{A}^{*, \delta} \cap L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P}\right)\right) \rightarrow L_{l-1}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)
$$

is a Fredholm operator for each $A \in \mathcal{A}(P, \alpha)$.
Then we have the following:

Proposition 3.2 (see Furuta [16, Proposition 4.2]) Let $X$ be a 4-manifold with cylindrical ends and with $b_{1}(X)=0$ and $b_{2}^{+}(X)=0$, and let $\mathcal{M}(P, \alpha)$ be the moduli space of instantons on an adapted $\mathrm{SU}(2)$-bundle $(P, \alpha)$. Suppose there is a compact set $K$ in $\mathcal{M}(P, \alpha)$ such that

$$
\left(D \Phi_{\tau}\right)_{A}: \operatorname{Ker} d_{A}^{*, \delta} \cap L_{l}^{2, \delta}\left(\wedge^{1}\left(\mathfrak{g}_{P}\right)\right) \rightarrow L_{l-1}^{2, \delta}\left(\wedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)
$$

is surjective for any $A \in p^{-1}(\mathcal{M}(P, \alpha)-K)$. Then there exists an open neighborhood $U$ of $K$ in $\mathcal{B}(P, \alpha)$ and a smooth $\mathcal{G}(P, \alpha)$-equivariant map $\sigma: \mathcal{A}(P, \alpha) \rightarrow$ $L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)$ supported in $p^{-1}(U)$ such that the following properties hold:
(1) For any $[A] \in \mathcal{M}^{\sigma+\tau}(P, \alpha):=p\left(\left(\Phi_{\tau}+\sigma\right)^{-1}(\{0\})\right)$, the derivative of $\Phi_{\tau}+\sigma$ at $A$,

$$
D\left(\Phi_{\tau}+\sigma\right)_{A}: \operatorname{Ker} d_{A}^{*, \delta} \cap L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P}\right)\right) \rightarrow L_{l-1}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right),
$$

is surjective.
(2) The irreducible part $\mathcal{M}^{* \sigma+\tau}(P, \alpha)=\mathcal{M}^{\sigma+\tau}(P, \alpha) \cap \mathcal{B}^{*}(P, \alpha)$ is a finite-dimensional smooth manifold and the tangent space $T_{[A]} \widetilde{\mathcal{M}}^{* \sigma+\tau} \widetilde{\mathcal{M}}^{* \sigma+\tau}(P, \alpha)$ of the framed moduli space $\widetilde{\mathcal{M}}^{* \sigma+\tau}(P, \alpha)=\widetilde{\mathcal{M}}^{\sigma+\tau}(P, \alpha) \cap \widetilde{\mathcal{B}}^{*}(P, \alpha)$ is isomorphic to the first cohomology,

$$
H_{A}^{1}=\operatorname{Ker} d_{A}^{+} / \operatorname{Im} d_{A} \cong \operatorname{Ker} d_{A}^{+} \cap \operatorname{Ker} d_{A}^{*, \delta} \subset L_{l}^{2, \delta},
$$

of the elliptic complex

$$
0 \rightarrow L_{l+1}^{2, \delta}\left(\bigwedge^{0}\left(\mathfrak{g}_{P}\right)\right) \xrightarrow{d_{A}} L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P}\right)\right) \xrightarrow{d_{A}^{+}} L_{l-1}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right) \rightarrow 0 .
$$

(3) For any $[A] \in \mathcal{M}_{\text {red }}(P, \alpha)$ we have $\sigma(A)=0$, and there exists a neighborhood $N$ of $[A]$ in $\mathcal{M}^{\sigma+\tau}(P, \alpha)$ with a homeomorphism $\varphi: N \rightarrow c \mathbb{C} P^{d}$ to the cone $c \mathbb{C} P^{d}$ over $\mathbb{C} P^{d}$ for some $d$ with $\varphi([A])$ the vertex of $c \mathbb{C} P^{d}$ whose restriction

$$
\left.\varphi\right|_{N-\{[A]\}}: N-\{[A]\} \rightarrow c \mathbb{C} P^{d}-\{h([A])\}
$$

is a $C^{\infty}$-diffeomorphism.
(4) $\mathcal{M}^{\sigma+\tau}(P, \alpha) \cap \bar{U}$ is compact.

Proof Since the second cohomology $H_{A}^{2}$ of the complex has finite dimension at each instanton $A$, a perturbation can be constructed over a local slice at $A$. Since $\mathcal{A}(P, \alpha)$ is a Hilbert manifold, we can use a $C^{\infty}$ cut-off function $\beta: \mathcal{B}(P, \alpha) \rightarrow \mathbb{R}$ defined by using the $L_{l}^{2, \delta}$-norm $\|a\|_{L_{l}^{2, \delta}}$, so that we can take a smooth partition of unity subordinated
to an open covering of the compact subset $K \subset \mathcal{M}(P, \alpha) \subset \mathcal{B}(P, \alpha)$ consisting of local slices at each $A$ to construct a perturbation $\sigma: \mathcal{A}(P, \alpha) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)$. This is a standard argument; see for example [24] and for the $L_{l}^{2, \delta}$-norm see [8].

### 3.4 Equivariant instantons over $\mathbb{R} \times S^{\mathbf{3}}$

Next we consider equivariant instantons over $\mathbb{R} \times S^{3}$ for the standard sphere $S^{3}$. In what follows, we use an identification $\mathbb{C}^{2} \cong \mathbb{H}$ given by $(z, w) \mapsto z+j w$, so that the left multiplication $x \mapsto a x$ for $x \in \mathbb{H}$ with $a \in \mathbb{H}$ is $\mathbb{C}$-linear, to identify $\mathrm{SU}(2)=\operatorname{Sp}(1)$. We fix an orientation $o(\mathbb{H})=1 \wedge i \wedge j \wedge k$ of $\mathbb{H}$. By noting that

$$
x=x_{0}+i x_{1}+j x_{2}+k x_{3}=x_{0}+i x_{1}+j\left(x_{2}-i x_{3}\right) \in \mathbb{H}
$$

we see that the orientation $o(\mathbb{H})$ is opposite to that induced from the standard one of $\mathbb{C}$ given by $o(\mathbb{C})=1 \wedge i$ and so the identification $\mathbb{C} \oplus \mathbb{C} \cong \mathbb{H}$ defined by $(z, w) \mapsto z+j \bar{w}$ gives an orientation-preserving diffeomorphism.

Definition 3.3 Let $\left(\tilde{Q}_{0}, \theta_{0}\right)$ be an adapted $\operatorname{SU}(2)$-bundle over the cylinder $\mathbb{R} \times S^{3}$ defined by $\tilde{Q}_{0}=\mathbb{R} \times S^{3} \times \operatorname{Sp}(1)$ with a pair $\theta_{0}=\left\{\theta_{0}^{-}, \theta_{0}^{+}\right\}$consisting of the trivial flat connection $\theta_{0}^{ \pm}$over $\pm(r, \infty) \times S^{3}$ for some $r>0$ with respect to the trivialization

$$
\begin{gathered}
\tau_{ \pm}:\left.\widetilde{Q}_{0}\right|_{ \pm(r, \infty) \times S^{3}= \pm(r, \infty) \times S^{3} \times \mathrm{Sp}(1) \rightarrow \pm(r, \infty) \times S^{3} \times \mathrm{Sp}(1)} \\
\tau_{ \pm}(t, y, q)=\left(t, y, y^{( \pm 1+1) / 2} q\right) \quad \text { for }(t, y, q) \in \pm(r, \infty) \times S^{3} \times \operatorname{Sp}(1)
\end{gathered}
$$

Then $\left(\tilde{Q}_{0}, \theta_{0}\right)$ admits an $\mathrm{SU}(2) \times \mathrm{SU}(2)-$ action

$$
g \cdot(t, y, q)=\left(t, e_{+} y e_{-}^{-1}, e_{-} q\right)
$$

for

$$
(t, y, q) \in \mathbb{R} \times S^{3} \times \mathrm{Sp}(1), \quad g=\left(e_{+}, e_{-}\right) \in \mathrm{Sp}(1) \times \mathrm{Sp}(1)
$$

to define an $(\mathrm{SU}(2) \times \mathrm{SU}(2))$-equivariant adapted $\mathrm{SU}(2)$-bundle over $\mathbb{R} \times S^{3}$ with $c_{2}\left(\widetilde{Q}_{0}, \theta_{0}\right)=1$. Note that under the trivialization $\tau_{ \pm}$, the $\operatorname{SU}(2) \times \operatorname{SU}(2)-$ action has the form

$$
g \cdot(t, y, q)=\left(t, e_{+} y e_{-}^{-1}, \alpha_{0}^{ \pm}(g) q\right), \quad \text { where } \alpha_{0}^{ \pm}(g)=e_{ \pm}
$$

for

$$
(t, y, q) \in \pm(r, \infty) \times S^{3} \times \operatorname{Sp}(1) \quad \text { and } \quad g=\left(e_{+}, e_{-}\right) \in \operatorname{Sp}(1) \times \operatorname{Sp}(1)
$$

If the action of a finite subgroup $\widetilde{G}$ of $\mathrm{SU}(2) \times \mathrm{SU}(2)$ on $S^{3} \subset \mathbb{H}$ is free, we call $\widetilde{G}$ a pseudofree subgroup of $\operatorname{SU}(2) \times \mathrm{SU}(2)$. Consider the quotient bundle $Q_{0}=\widetilde{Q}_{0} / \widetilde{G}$
over $\mathbb{R} \times S^{3} / \widetilde{G}$ with the flat connection $\alpha_{0}^{ \pm}$on $\left.Q_{0}\right|_{ \pm(r, \infty) \times S^{3} / \widetilde{G}}$ induced by the trivial flat connection $\theta_{0}^{ \pm}$on $\pm(r, \infty) \times S^{3} \times \operatorname{Sp}(1)$. The adapted bundle $\left(Q_{0}, \alpha_{0}\right)$ with $\alpha_{0}=\left\{\alpha_{0}^{-}, \alpha_{0}^{+}\right\}$and $c_{2}\left(Q_{0}, \alpha_{0}\right)=1 /|\widetilde{G}|$ is called the adapted $\mathrm{SU}(2)$-bundle associated with a pseudofree subgroup $\widetilde{G}$ of $\mathrm{SU}(2) \times \mathrm{SU}(2)$.

Remark 3.4 Let $Y=S^{3} / G$ be the 3-dimensional spherical space form obtained by taking a quotient of $S^{3}$ by a finite group $G \subset \mathrm{SO}(4)$ acting freely on $S^{3} \subset \mathbb{R}^{4}$ by matrix multiplication. The action $\left(e_{+}, e_{-}\right) \cdot x=e_{+} x e_{-}^{-1}$ for $x \in \mathbb{H}$ of $\mathrm{Sp}(1) \times \operatorname{Sp}(1)$ on $\mathbb{H}$ induces the projection $\pi: \mathrm{SU}(2) \times \mathrm{SU}(2) \rightarrow \mathrm{SU}(2) \times{ }_{\{ \pm 1\}} \mathrm{SU}(2) \cong \mathrm{SO}(4)$. If we can take a lift $\widetilde{G}$ of $G$, which means that $\widetilde{G}$ is the image of an injective homomorphism $\iota: G \rightarrow \mathrm{SU}(2) \times \mathrm{SU}(2)$ with $\pi \circ \iota=\mathrm{id}_{\mathrm{SO}(4)}$, then $\widetilde{G}$ is a pseudofree subgroup of $\mathrm{SU}(2) \times \mathrm{SU}(2)$ acting on $S^{3} \subset \mathbb{H}$ as above.

Then we have the following proposition:
Proposition 3.5 (see Furuta [16, Lemmas 5.1 and 5.2]) Let ( $Q_{0}, \alpha_{0}$ ) be the adapted $\mathrm{SU}(2)$-bundle over $\mathbb{R} \times S^{3} / \widetilde{G}$ associated to a pseudofree subgroup $\widetilde{G}$ of $\mathrm{SU}(2) \times \mathrm{SU}(2)$ as in Definition 3.3. Then the moduli space $\mathcal{M}\left(Q_{0}, \alpha_{0}\right)$ is regular and diffeomorphic to $\mathbb{R}$.

Proof Let $f: S^{4}-\{0, \infty\} \rightarrow \mathbb{R} \times S^{3}$ be the $\widetilde{G}$-equivariant conformal equivalence. Then $\widetilde{G}$-invariant instantons on the $\widetilde{G}$-equivariant adapted bundle $\left(\widetilde{Q}_{0}, \theta_{0}\right)$ over $\mathbb{R} \times S^{3}$ with finite energy $c_{2}\left(\tilde{Q}_{0}, \theta_{0}\right)=1$ have the pullback over $S^{4}-\{0, \infty\}$ and extends across $\{0, \infty\}$ uniquely by Uhlenbeck's removable singularity theorem [34] to obtain an $\widetilde{G}$-invariant instantons on a $\widetilde{G}$-equivariant $\operatorname{SU}(2)$-bundle $\widetilde{Q}$ over $S^{4}$ with $c_{2}(\widetilde{Q})=1$. This correspondence induces a diffeomorphism $\mathcal{M}_{\widetilde{G}}\left(\widetilde{Q}_{0}, \theta_{0}\right) \rightarrow \mathcal{M}_{\widetilde{G}}(\widetilde{Q})$ between moduli spaces of $\widetilde{G}$-invariant instantons. Then take the quotient by $\widetilde{G}$ to obtain a diffeomorphism $\mathcal{M}\left(Q_{0}, \alpha\right) \rightarrow \mathcal{M}(Q)$ and the assertion follows from the fact that $\mathcal{M}(Q)$ is regular and diffeomorphic to $\mathbb{R}$ by Lemmas 5.1 and 5.2 in [16].

Now we introduce a notion of positivity and negativity of spherical space forms, which was introduced by Furuta in the context of orbifolds [16].

Definition 3.6 (see [16, Definition 2.1]) A closed 3-manifold $Y$ is called a positive (resp. negative) spherical space form - positive (resp. negative) for short - if $Y \cong$ $S^{3} / G$ with a finite group $G \subset \operatorname{Sp}(1)$ acting on $S^{3} \subset \mathbb{H}$ by the left (resp. right) multiplication,

$$
g \cdot y=g y \quad \text { (resp. } g \cdot y=y g^{-1} \text { ) } \quad \text { for } y \in S^{3} \subset \mathbb{H} \text { and } g \in G \subset \operatorname{Sp}(1) .
$$

Definition 3.7 (see [16, Section 5, before Lemma 5.3]) If $Y=S^{3} / G$ is a positive (resp. negative) spherical space form and $G$ is the corresponding subgroup of $\operatorname{Sp}(1)$, then $G$ can be embedded into the group $\mathrm{SO}(4)=\operatorname{Sp}(1) \times{ }_{\{ \pm 1\}} \mathrm{Sp}(1)$ and we regard $G$ as a subgroup of $\mathrm{SO}(4)$ by the identification

$$
G \subset \operatorname{Sp}(1) \subset \operatorname{Sp}(1) \times_{\{ \pm 1\}}\{ \pm 1\} \subset \mathrm{SO}(4)=\operatorname{Sp}(1) \times_{\{ \pm 1\}} \operatorname{Sp}(1)
$$

or

$$
G \subset S p(1) \subset\{ \pm 1\} \times_{\{ \pm 1\}} S p(1) \subset \mathrm{SO}(4)=\mathrm{Sp}(1) \times_{\{ \pm 1\}} \mathrm{Sp}(1),
$$

respectively, and call $G$ a positive (resp. negative) subgroup of $\mathrm{SO}(4)$. In this case, we can take a lift

$$
\iota_{\text {pos }}: G \subset \operatorname{Sp}(1) \rightarrow \widetilde{G}=G \times\{1\} \subset \operatorname{Sp}(1) \times \operatorname{Sp}(1)
$$

or

$$
\iota_{\mathrm{neg}}: G \subset \mathrm{Sp}(1) \rightarrow \widetilde{G}=\{1\} \times G \subset \mathrm{Sp}(1) \times \operatorname{Sp}(1)
$$

respectively, to define a $G$-action on the adapted bundle ( $\widetilde{Q}_{0}, \theta_{0}$ ) by composing with $\iota_{\text {pos }}$ (resp. $\iota_{\text {neg }}$ ). We denote the representation corresponding to the inclusion $G \subset \operatorname{Sp}(1)$ by $\rho: G \hookrightarrow \operatorname{Sp}(1)$ acting on fibers $\mathrm{Sp}(1)$ by left multiplication. Then we call the quotient adapted bundle ( $Q_{0}, \alpha_{0}$ ) obtained by taking the quotient of ( $\tilde{Q}_{0}, \theta_{0}$ ) by $G$ the adapted $\operatorname{SU}(2)$-bundle over $\mathbb{R} \times Y$ of $c_{2}\left(Q_{0}, \alpha_{0}\right)=1 / m$ associated with the positive (resp. negative) subgroup $G_{1}$.

Remark 3.8 The $\mathrm{SO}(4)=\mathrm{SU}(2) \times_{\{ \pm 1\}} \mathrm{SU}(2)$-action on $S^{3}=\mathbb{H} \cup\{\infty\}$ is given by

$$
\left[e_{+}, e_{-}\right] \cdot x=e_{+} x e_{-}^{-1}, \quad x \in S^{3},\left[e_{+}, e_{-}\right] \in \operatorname{Sp}(1) \times_{\{ \pm 1\}} \mathrm{Sp}(1) .
$$

Note that we have an identification $\mathbb{H} \ni x=z+j w \mapsto(z, w) \in \mathbb{C} \oplus \mathbb{C}$, so that $\operatorname{Sp}(1)$ is identified with $\mathrm{SU}(2)$ under the left multiplication. If $G=\mathbb{Z}_{m} \subset U(1) \subset \mathrm{Sp}(1) \subset$ $\operatorname{Sp}(1) \times_{\{ \pm 1\}}\{ \pm 1\}$, where $U(1)=\left\{e^{i \theta} \mid \theta \in \mathbb{R}\right\}$ and $\left[e_{+}, e_{-}\right]=[\zeta, 1] \in G$, then

$$
[\zeta, 1] \cdot x=\zeta(z+j w)=\zeta z+j \zeta^{-1} w .
$$

On the other hand, the orientation $o\left(\mathbb{C}^{2}\right)$ induced from the standard one $o(\mathbb{C})=1 \wedge i$ is opposite to the orientation $o(\mathbb{H})=1 \wedge i \wedge j \wedge k$ of

$$
\mathbb{H}=\mathbb{R}+\mathbb{R} i+\mathbb{R} j+\mathbb{R} k=\mathbb{C} \oplus j \mathbb{C} \cong \mathbb{C}^{2}
$$

so that $l: \mathbb{C}^{2} \ni(z, w) \mapsto z+j \bar{w} \in \mathbb{H}$ gives the orientation-preserving diffeomorphism and

$$
\left(\iota^{-1} \circ[\zeta, 1] \circ \iota\right)(z, w)=(\zeta z, \zeta w),
$$

implying $S^{3} / G \cong L(m, 1)$ is positive. Similarly if $G=\mathbb{Z}_{m} \subset U(1) \subset \operatorname{Sp}(1) \subset$ $\{ \pm 1\} \times \times_{\{ \pm 1\}} \operatorname{Sp}(1)$ and $\left[e_{+}, e_{-}\right]=[1, \zeta] \in G$ then

$$
[1, \zeta] \cdot x=(z+j w) \zeta^{-1}=\zeta^{-1} z+j \zeta^{-1} w
$$

and

$$
\left(\iota^{-1} \circ[1, \zeta] \circ \iota\right)(z, w)=\left(\zeta^{-1} z, \zeta w\right)
$$

so that $S^{3} / G \cong L(m,-1)$ is negative.

The following proposition is a key to studying behaviors of flat connections after the "sliding ends" phenomenon:

Proposition 3.9 (see [16, Lemma 5.3]) Let $G$ be a finite group acting on $S^{3}$ freely. Let $\left(\widetilde{Q}_{1}, \theta_{1}\right)$ be a $G$-equivariant adapted $\mathrm{SU}(2)$-bundle $\widetilde{Q}_{1} \rightarrow \mathbb{R} \times S^{3}$ with the trivial flat connections $\theta_{1}=\left\{\theta_{1}^{ \pm}\right\}$over $\mathbb{R}_{ \pm} \times S^{3}, c_{2}\left(\widetilde{Q}_{1}, \theta_{1}\right)=1$, and the $G$-action on $\widetilde{Q}_{1}$ defined by representations $\alpha_{1}^{ \pm}: G \rightarrow \mathrm{SU}(2)$ with respect to the trivializations of $\theta_{1}^{ \pm}$. Suppose there exists a $G$-invariant instanton $\widetilde{A}_{1}$ on $\left(\widetilde{Q}_{1}, \theta_{1}\right)$. Then the following properties hold:
(1) If $\alpha_{1}^{+}=1$, then $S^{3} / G$ is negative and $\alpha_{1}^{-}$is conjugate to the inclusion $\rho: G \hookrightarrow$ $\mathrm{Sp}(1)$.
(2) If $S^{3} / G$ is positive and $\alpha_{1}^{+}$is the inclusion $\rho: G \hookrightarrow \operatorname{Sp}(1)$ then $\alpha_{1}^{-}=\varepsilon$ and $\rho$ is conjugate to $\varepsilon \rho$ for some homomorphism $\varepsilon: G \rightarrow\{ \pm 1\}$.

Proof The proof is the same as in [16] for the case of $G$-equivariant instantons on the $G$-equivariant $\operatorname{SU}(2)$-bundle $\widetilde{Q}_{1}$ over $S^{4}$ under an identification with $G$-equivariant instantons on an adapted $G$-equivariant $\operatorname{SU}(2)$-bundle $\left(\widetilde{Q}_{1}, \theta_{1}\right)$ over $\mathbb{R}_{+} \times S^{3}$. Note here that the conformal map

$$
f: \mathbb{R} \times S^{3} \rightarrow S^{4}=\mathbb{H} \cup\{\infty\}, \quad f(t, y)=\left(e^{t} y\right)^{-1}
$$

is orientation-preserving with respect to the standard orientation $o(\mathbb{H})=1 \wedge i \wedge j \wedge k$. However, the map $f$ sends the positive end $\mathbb{R}_{+} \times S^{3}$ to the punctured unit ball $B_{1}-\{0\}$, where $B_{1}=\{x \in \mathbb{H}| | x \mid \leq 1\}$, and the induced orientation on the boundary $S^{3}=\partial B_{1}$ of $B_{1} \subset \mathbb{H}$ is opposite to that of the standard orientation $S^{3}$ in $\mathbb{R} \times S^{3}$. On the other hand, self-dual connections change to anti-self-dual connections if we change the orientation of the 4-manifold. Hence, the "positivity" (resp. "negativity") in our proposition coincides with that of Lemma 5.3 in [16].

### 3.5 The virtual dimension of the moduli space

To calculate the virtual dimension of moduli spaces of instantons over 4-manifolds with cylindrical ends, it is easier to use the addition property for indices [8, Section 3.3]. First we recall:

Definition 3.10 Let $\left(P_{k}, \alpha_{k}\right)$ for $k=1,2$ be an adapted $\mathrm{SU}(2)$-bundle over a $4-$ manifold $X_{k}$ with cylindrical ends $\mathbb{R}_{+} \times Y_{k i}$ indexed by $i \in I_{k}$ for a finite set $I_{k}$ containing 0 and with an identification $Y_{10}=Y=-Y_{20}$ for the $i=0^{\text {th }}$ component, and a fixed bundle isomorphism $h:\left.\left.P_{1}\right|_{\mathbb{R}_{+} \times Y_{10}} \rightarrow P_{2}\right|_{\mathbb{R}_{+} \times Y_{20}}$ such that $\alpha_{10}=h^{*} \alpha_{20}$. For a fixed parameter $T>0$, we define a gluing $X_{1} \#_{(T)} X_{2}$ of $X_{1}-\left((2 T, \infty) \times Y_{10}\right)$ and $X_{2}-\left((2 T, \infty) \times Y_{20}\right)$ under the identification $\left(t_{1}, y_{1}\right) \sim\left(t_{2}, y_{2}\right)$ if $\left(t_{2}, y_{2}\right)=$ $\left(2 T-t_{1}, y_{1}\right)$ for $\left(t_{1}, y_{1}\right) \in[T, 2 T] \times Y_{10},\left(t_{2}, y_{2}\right) \in[T, 2 T] \times Y_{20}$. The gluing $P_{1} \#_{(T)} P_{2}$ is defined naturally by using the isomorphism $h:\left.\left.P_{1}\right|_{\mathbb{R}_{+} \times Y_{10}} \rightarrow P_{2}\right|_{\mathbb{R}_{+} \times Y_{20}}$. Set $\alpha_{1} \# \alpha_{2}=\alpha_{1} \cup \alpha_{2}-\left\{\alpha_{10}, \alpha_{20}\right\}$. Then $\left(P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}\right)$ defines an adapted $\mathrm{SU}(2)$-bundle over $X_{1} \#_{(T)} X_{2}$.

In fact, the isomorphism class of $\left(P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}\right)$ does not depend on the parameter $T$, so we omit the parameter $T$ in the notation $\#_{(T)}$ of the gluing if we do not need to specify it. Then, by additivity of indices of elliptic operators under connected sums, we have the following:

Proposition 3.11 Let $X$ be a Riemannian 4-manifold with cylindrical ends $\mathbb{R}_{+} \times Y_{i}$ for $i \in\{1, \ldots, s+1\}$ and $b_{1}(X)=0, b_{2}^{+}(X)=0$, where $Y_{s+1}$ is a rational homology 3-sphere and the $Y_{i}$ are spherical space forms $Y_{i} \cong S^{3} / G_{i}$ for $i \in\{1, \ldots, s\}$. Suppose that $Y_{1}$ is a positive spherical space form $S^{3} / G_{1}$ with $\left|G_{1}\right|=m$. Let $(Q, \beta)$ be an adapted $\mathrm{SU}(2)$-bundle over $\mathbb{R} \times Y_{1}$ of $c_{2}(Q, \beta)=1 / \mathrm{m}$ associated with the positive subgroup $G_{1}$ equipped with flat connections $\beta=\left\{\beta_{ \pm}\right\}$on each ends $\mathbb{R}_{ \pm} \times Y_{1}$, where $\beta_{+}=\rho_{1}$ is the inclusion $\rho_{1}: G_{1} \hookrightarrow \operatorname{Sp}(1)$ and $\beta_{-}=\theta$. Let $\left(P_{0}, \theta\right)$ be the trivial adapted $\mathrm{SU}(2)$-bundle $P_{0}=X \times \mathrm{SU}(2)$ equipped with trivial connections $\theta=\left\{\theta_{i}\right\}$ on each ends. If $(P, \alpha)=\left(P_{0} \# Q, \theta \# \beta\right)$ is the connected sum of $\left(P_{0}, \theta\right)$ and $(Q, \beta)$ along $Y_{1}$. Then we have the following properties:
(1) The virtual dimension of the moduli space $\mathcal{M}(P, \alpha)$ is equal to that of $\mathcal{M}(Q, \beta)$.
(2) If $\left(Q^{\prime}, \beta^{\prime}\right)$ is an adapted $\mathrm{SU}(2)$-bundle over $\mathbb{R} \times Y_{1}$ of $c_{2}\left(Q^{\prime}, \beta^{\prime}\right)=0$ equipped with flat connections $\beta^{\prime}=\left\{\beta_{ \pm}^{\prime}\right\}$ on each ends $\mathbb{R}_{ \pm} \times Y_{1}$, where $\beta_{+}^{\prime}$ corresponds to a representation $\varepsilon: G_{1} \rightarrow\{ \pm 1\}$ and $\beta_{-}^{\prime}=\theta$, and let $\left(P^{\prime}, \alpha^{\prime}\right)=\left(P_{0} \# Q^{\prime}, \theta \# \beta^{\prime}\right)$
be the adapted bundle obtained by the connected sum of $\left(P_{0}, \theta\right)$ and $\left(Q^{\prime}, \beta^{\prime}\right)$ along $Y_{1}$, then the virtual dimension of the moduli space $\mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)$ is equal to -3 .
(3) If $Y_{i}=S^{3} / G_{i}$ is a negative spherical space form with $\left|G_{i}\right|=\left|G_{1}\right|$ for some $i \neq 1$ and let $\left(Q^{\prime \prime}, \beta^{\prime \prime}\right)$ be an adapted $\mathrm{SU}(2)-$ bundle over $\mathbb{R} \times Y_{i}$ of $c_{2}\left(Q^{\prime \prime}, \beta^{\prime \prime}\right)=1 / m$ associated with a negative subgroup $G_{i}$ equipped with flat connections $\beta^{\prime \prime}=$ $\left\{\beta_{ \pm}^{\prime \prime}\right\}$ on each ends $\mathbb{R}_{ \pm} \times Y_{i}$, where $\beta_{+}^{\prime \prime}=\theta$ and $\beta_{-}^{\prime \prime}=\rho_{i}$ is the flat connection corresponding to the inclusion $\rho_{i}: G_{i} \hookrightarrow \operatorname{Sp}(1)$. Let $\left(P^{\prime \prime}, \alpha^{\prime \prime}\right)$ be an adapted $\mathrm{SU}(2)$-bundle such that the connected sum ( $\left.P^{\prime \prime} \# Q^{\prime \prime}, \alpha^{\prime \prime} \# \beta^{\prime \prime}\right)$ of $\left(P^{\prime \prime}, \alpha^{\prime \prime}\right)$ and $\left(Q^{\prime \prime}, \beta^{\prime \prime}\right)$ along $Y_{i}$ is isomorphic to $(P, \alpha)$. Then the virtual dimension of the moduli space $\mathcal{M}\left(P^{\prime \prime}, \alpha^{\prime \prime}\right)$ is $-\operatorname{dim} \Gamma_{\rho_{i}}$, where $\Gamma_{\rho_{i}}$ is the stabilizer of $\rho_{i}$ in the gauge transformation group of $\left.Q^{\prime \prime}\right|_{Y_{i}}$.

Proof The virtual dimension of the moduli space $\mathcal{M}(P, \alpha)$ is equal to the index $\operatorname{ind}^{+}(P, \alpha)$ of the deformation operator $D_{A}=-d_{A}^{*} \oplus d_{A}^{+}$for a connection $A$ on ( $P, \alpha$ ) acting on sections with positively weighted norms,

$$
D_{A}=-d_{A}^{*} \oplus d_{A}^{+}: L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P}\right)\right) \rightarrow L_{l-1}^{2, \delta}\left(\bigwedge^{0}\left(\mathfrak{g}_{P}\right) \oplus \bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)
$$

which can be calculated as the index of the operator $D_{A}^{\text {APS }}$ over the 4 -manifold $W$ with boundary $Y$ under Atiyah-Patodi-Singer boundary condition (see [8, Section 3.3.2, Proposition 3.19]). The statements (1) and (3) follows from the addition formula for indices under the connected sum $(P, \alpha)=\left(P^{\prime}, \alpha^{\prime}\right) \#(Q, \beta)$ along the $i^{\text {th }}$ component with flat connection $\alpha_{i}^{\prime}=\beta_{-}$and $\alpha_{i}=\beta_{+}$[8, Propositions 3.9 and 3.10],

$$
\operatorname{ind}^{+}(P, \alpha)=\operatorname{ind}^{+}\left(P^{\prime}, \alpha^{\prime}\right)+\operatorname{ind}^{+}(Q, \beta)+\operatorname{dim} \Gamma_{\alpha_{i}^{\prime}}
$$

where $\Gamma_{\alpha_{i}^{\prime}}$ is the stabilizer of $\alpha_{i}^{\prime}$ in the gauge transformation group of $\left.P\right|_{Y_{i}}$. For the statement (2), we now apply (1) to see ind ${ }^{+}\left(P^{\prime}, \alpha^{\prime}\right)=\operatorname{ind}^{+}\left(Q^{\prime}, \beta^{\prime}\right)$, and ind ${ }^{+}\left(Q^{\prime}, \beta^{\prime}\right)=-3$ follows from Proposition 2.6 of [18] by noting that $\rho\left(Y_{1}, \theta\right)=0$ and $\rho\left(Y_{1}, \varepsilon\right)=0$ since $\varepsilon$ is a nontrivial central representation such that ad $\varepsilon=1$.

### 3.6 Chern-Simons invariants and compactness of the moduli

Instanton moduli spaces on 4 -manifolds with product ends in general fail to be compact due to either "bubbling" (when a divergent sequence of instantons has curvatures concentrating to a point in the 4 -manifold) or "sliding ends" (when the curvatures recede to infinity along a cylindrical end). These phenomena can be controlled by Chern-Simons invariants.

Here we recall the definitions.
Definition 3.12 (see [15]) Let $Y$ be a closed oriented 3-manifold, and $Q \rightarrow Y$ be a principal $\mathrm{SU}(2)$-bundle with a flat connection $\alpha$ on $Q$. Let $X$ be an oriented smooth 4-manifold with cylindrical ends $\mathbb{R} \times\left(Y \sqcup Y^{\prime}\right)$ for some disjoint union $Y^{\prime}$ of closed oriented 3-manifolds, and ( $P, \widetilde{\alpha}$ ) be an adapted $\mathrm{SU}(2)$-bundle over $X$ such that $\left(\left.P\right|_{\mathbb{R}_{+} \times Y},\left.\tilde{\alpha}\right|_{\mathbb{R}_{+} \times Y}\right) \cong\left(p_{Y}^{*} Q, p_{Y}^{*} \alpha\right)$ for the projection $p_{Y}: \mathbb{R}_{+} \times Y \rightarrow Y$ and $\left(\left.P\right|_{\mathbb{R}_{+} \times Y^{\prime}},\left.\widetilde{\alpha}\right|_{\mathbb{R}_{+} \times Y^{\prime}}\right) \cong\left(\mathbb{R}_{+} \times Y^{\prime} \times \operatorname{SU}(2), \theta\right)$ for the trivial flat connection $\theta$. Then the Chern-Simons invariant of $(Y, \alpha)$ is defined to be

$$
\operatorname{cs}(Y, \alpha) \equiv c_{2}(P, \tilde{\alpha})(\bmod \mathbb{Z}) .
$$

Note that $\operatorname{cs}(Y, \alpha)$ does not depend on the choice of the adapted bundle $(P, \widetilde{\alpha}) \rightarrow X$ as above. In fact, if we take another $\left(P^{\prime}, \tilde{\alpha}^{\prime}\right) \rightarrow X$ then the bundle $P \# P^{\prime}$ over $X \cup(-X)$ obtained by gluing along ends gives $c_{2}(P, \widetilde{\alpha})-c_{2}\left(P^{\prime}, \tilde{\alpha}^{\prime}\right)=c_{2}\left(P \# P^{\prime}\right) \in \mathbb{Z}$.

Definition 3.13 [18] Let $Q$ be an $\mathrm{SU}(2)$-bundle over a closed oriented 3-manifold $Y$ and let $\mathbb{R} \times Q \rightarrow \mathbb{R} \times Y$ be the pullback by the projection $\mathbb{R} \times Y \rightarrow Y$. Let $\alpha_{ \pm}$be flat connections on $Q$ viewed as flat connection on the ends $\mathbb{R}_{ \pm} \times Y$ of the cylinder $\mathbb{R} \times Y$. Then the relative Chern-Simons invariant $\operatorname{cs}\left(Y, \alpha_{-}, \alpha_{+}\right)$is defined to be

$$
\operatorname{cs}\left(Y, \alpha_{-}, \alpha_{+}\right)=c_{2}\left(\mathbb{R} \times Q,\left\{\alpha_{-}, \alpha_{+}\right\}\right) \in \mathbb{R}
$$

Note that $\operatorname{cs}\left(Y, \alpha_{-}, \alpha_{+}\right)-\operatorname{cs}\left(Y, g^{*} \alpha_{-}, \alpha_{+}\right) \in \mathbb{Z}$ for any $g \in \operatorname{Aut}(Q)$, and $\operatorname{cs}\left(Y,-, \alpha_{+}\right)$ descends to a locally constant $\mathbb{R} / \mathbb{Z}$-valued function on the space $\mathcal{R}(Y, \mathrm{SU}(2))$ of all conjugacy classes of $\mathrm{SU}(2)$-representations of the fundamental group $\pi_{1}(Y)$ of $Y$. Since $\mathcal{R}(Y, \mathrm{SU}(2))$ is compact, the set of all values $\operatorname{cs}(Y, \gamma, \alpha)(\bmod \mathbb{Z})$ for all flat connections $\alpha$ and $\gamma$ on $Q$ is finite.

Definition 3.14 [18] Let $b: \mathbb{R} / \mathbb{Z} \rightarrow(0,1]$ be the obvious bijection. For a rational homology 3-sphere $Y$ and a flat connection $\alpha$ on a $\operatorname{SU}(2)$-bundle $Q$ over $Y$, we define its minimum Chern-Simons invariant $\tau(Y, \alpha)$ by

$$
\tau(Y, \alpha)=\min \{b(\operatorname{cs}(Y, \gamma, \alpha)) \in(0,1] \mid \gamma \text { a flat connection on } Q\} .
$$

Then we have the following compactness result:
Proposition 3.15 Let $X$ be a 4-manifold with cylindrical ends $\mathbb{R}_{+} \times Y_{i}$ for $i \in I$ and $(P, \alpha)$ be an adapted $\mathrm{SU}(2)$-bundle over $X$ with

$$
0<c_{2}(P, \alpha)=\epsilon=\min \left\{\tau\left(Y_{i}, \alpha_{i}\right) \mid i \in I\right\} \leq \frac{1}{2} .
$$

Suppose that $H^{1}\left(Y_{i} ;\right.$ ad $\left.\gamma\right)=\{0\}$ for any flat $\mathrm{SU}(2)$-connection $\gamma$ over each component $Y_{i}$ with $\operatorname{cs}\left(Y_{i}, \gamma\right) \equiv \epsilon(\bmod \mathbb{Z})$. Fix a Riemannian metric on $X$ with product ends. Let $\mathcal{M}^{\sigma}(P, \alpha)$ be the moduli space of $\sigma$-instantons $A$ on $(P, \alpha)$, that is, connections $A$ satisfying the equation $F_{A}^{+}+\sigma(A)=0$, where $\sigma: \mathcal{A}(P, \alpha) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)$ is a smooth perturbation such that
(1) $\|\sigma(A)\|_{L^{2}(X)}^{2}<4 \pi^{2} \epsilon$,
(2) there exists a compact set $\Omega \subset W=X-\coprod_{i}\left(\mathbb{R}_{+} \times Y_{i}\right)$ such that
(a) $\operatorname{supp} \sigma(A) \subset \Omega$ for all $A \in \mathcal{A}(P, \alpha)$, and
(b) $\sigma(A)=0$ if $\left\|F_{A}\right\|_{L^{2}(\Omega)}^{2}>4 \pi^{2}$.

Then, for any sequence $\left\{\left[A_{n}\right]\right\}$ in $\mathcal{M}^{\sigma}(P, \alpha)$, there exists a subsequence $\left\{n^{\prime}\right\}$ of $\{n\}$ and a sequence of gauge transformations $\left\{g_{n^{\prime}}\right\}$ such that one of the following holds:
(1) $\left\{g_{n^{\prime}}^{*} A_{n^{\prime}}\right\}$ converges to a $\sigma$-instanton $A^{\prime}$ on the bundle $(P, \alpha)$ over $X$ in $C_{\text {loc }}^{\infty}-$ topology.
(2) $\left\{g_{n^{\prime}}^{*} A_{n^{\prime}}\right\}$ converges to a $\sigma$-instanton $A^{\prime}$ on a limiting adapted bundle ( $P^{\prime}, \alpha^{\prime}$ ) over $X$ in $C_{\text {loc }}^{\infty}$-topology, and there exists a unique $i \in I$ and a sequence $\left\{T_{n^{\prime}}\right\}$ with $T_{n^{\prime}}>0$ and $\lim _{n^{\prime} \rightarrow \infty} T_{n^{\prime}}=+\infty$ such that the sequence of the pullback connections $\left\{c_{T_{n^{\prime}}}^{*}\left(\left.g_{n^{\prime}}^{*} A_{n^{\prime}}\right|_{\mathbb{R}_{+} \times Y_{i}}\right)\right\}$ by the translation $c_{T_{n^{\prime}}}$ with $T_{n^{\prime}}$ over $\left[-T_{n^{\prime}}, \infty\right) \times Y_{i}$ converges to an instanton $B_{i}^{\prime}$ on an adapted bundle ( $Q_{i}^{\prime}, \beta_{i}^{\prime}$ ) over the cylinder $\mathbb{R} \times Y_{i}$ in $C_{\mathrm{loc}}^{\infty}$-topology such that

$$
c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0, \quad c_{2}\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)=\epsilon,
$$

where

$$
\alpha_{j}^{\prime}=\alpha_{j} \quad \text { for } j \neq i, \quad \alpha_{i}^{\prime}=\beta_{i}^{\prime-}, \quad \beta_{i}^{\prime+}=\alpha_{i} .
$$

Proof Each term of the sequence of $\sigma$-instanton $\left\{\left[A_{n}\right]\right\} \subset \mathcal{M}^{\sigma}(P, \alpha)$ satisfies the perturbed equation $F_{A_{n}}^{+}+\sigma\left(A_{n}\right)=0$. Since the support of the perturbation $\sigma$ is contained in a compact subset $\Omega \subset W$ away from the cylindrical ends $\mathbb{R}_{+} \times Y_{i}$, we see as in the proof of Theorem 5.4 in [8] that the sequence $\left\{\left[A_{n}\right]\right\}$ has a weak chain convergent subsequence. By the condition $\left\|\sigma\left(A_{n}\right)\right\|_{L^{2}}^{2}<4 \pi^{2} \epsilon$, we have

$$
\left\|F_{A_{n}}\right\|_{L^{2}}^{2}=8 \pi^{2} \epsilon+2\left\|\sigma\left(A_{n}\right)\right\|_{L^{2}}^{2}<8 \pi^{2} \epsilon+2 \cdot 4 \pi^{2} \epsilon=2 \cdot 8 \pi^{2} \epsilon \leq 8 \pi^{2},
$$

and since $\sigma(A)=0$ for those connections $A$ with $\left\|F_{A}\right\|_{L^{2}(\Omega)}^{2}>4 \pi^{2}$, we see that the perturbation term vanishes for connections with the energy concentrating on $\Omega$. Therefore, we can apply Uhlenbeck's removable singularity theorem [34] to see that
the bubbling does not occur. Since $\tau\left(Y_{i}, \alpha_{i}\right) \geq \epsilon$ for all $i \in I$, the sequence has a chain-convergent subsequence $\left[8\right.$, Section 5.1] with a limit given by $\pi$-instanton $A^{\prime}$ on a limiting adapted bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ with $\lim _{n \rightarrow \infty}\left\|\sigma\left(A_{n}\right)\right\|_{L^{2}}=\left\|\sigma\left(A^{\prime}\right)\right\|_{L^{2}}<4 \pi^{2} \epsilon$ and at most "one-term chain" from $\alpha_{i}^{\prime}$ to $\alpha_{i}$ with $\tau\left(Y_{i}, \alpha_{i}\right)=\epsilon$ over some $\mathbb{R} \times Y_{i}$ (possibly empty). If the limit has a one-term chain, an instanton $B_{i}^{\prime}$ is formed on some limiting bundle $\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)$ over $\mathbb{R} \times Y_{i}$ with $\beta_{i}^{\prime-}=\alpha_{i}^{\prime}$ and $\beta_{i}^{\prime+}=\alpha_{i}$ and satisfies the conservation of the topological charge

$$
\epsilon=c_{2}(P, \alpha)=c_{2}\left(P^{\prime}, \alpha^{\prime}\right)+c_{2}\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)=c_{2}\left(P^{\prime}, \alpha^{\prime}\right)+\epsilon,
$$

so that $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0$, which corresponds to (2). The other cases correspond to (1).

### 3.7 Perturbation on ends of the moduli space

In the following discussion, we need a perturbation which works even after bubbling or sliding ends occur. In [7], Donaldson used a holonomy of the connections to perturb (holonomy perturbation) the moduli space of flat connections after bubbling to prove his Theorem A for smooth negative-definite 4-manifolds with nontrivial fundamental groups. Here we use a variant of the formulation given by Kronheimer in [23]. It is easier in our case since we know that the bubbling does not occur.

Let $X$ be a 4 -manifold with cylindrical ends $\mathbb{R}_{+} \times Y_{i}$ for $i \in I$ and $\left(P^{\prime}, \alpha^{\prime}\right)$ be an adapted $\mathrm{SU}(2)$-bundle over $X$. Fix a Riemannian metric on $X$ with product ends. Let $B$ be a smooth embedded ball in $X$ and $q: S^{1} \times B \rightarrow X$ be a smooth submersion with $q(1, x)=x$ for all $x \in B$. Let $\omega \in \Omega_{+}^{2}(X)$ be a self-dual 2 -form with $\operatorname{supp} \omega \subset B$. For a smooth connection $A$ in $P^{\prime} \rightarrow X$, we denote by $\operatorname{Hol}_{q_{x}}(A) \in \operatorname{Aut}\left(P_{x}^{\prime}\right)$ the holonomy of $A$ around the loop $q_{x}: S^{1} \rightarrow X$ given by $q_{x}(z)=q(z, x)$. Then we have a holonomy $\operatorname{map} \operatorname{Hol}_{q}(A): B \rightarrow \Gamma\left(\left.\mathfrak{g l}_{P^{\prime}}\right|_{B}\right)$, where $\mathfrak{g l}_{P^{\prime}}=P^{\prime} \times{ }_{\mathrm{Ad}} \mathfrak{g l}_{2}$ with $\operatorname{Ad}(g) a=g a g^{-1}$ for $g \in \mathrm{SU}(2)$ and $a \in \mathfrak{g l}_{2}$, and define $\omega \otimes \operatorname{Hol}_{q}(A) \in \Omega_{+}^{2}\left(\mathfrak{g l}_{2}\right)$ by extending by zero.
Let $\psi: \mathfrak{g l}_{P^{\prime}} \rightarrow \mathfrak{s u}_{P^{\prime}}=\mathfrak{g}_{P^{\prime}}$ be the orthogonal bundle projection and $\rho_{\mu}: \mathbb{R} \rightarrow[0,1]$ be a smooth cut-off function satisfying $\rho_{\mu}(x)=0$ for $|x| \leq \mu, \rho_{\mu}(x)=1$ for $|x| \geq 2 \mu$ with $0 \leq\left|\rho_{\mu}^{\prime}(x)\right| \leq 1 / \mu$ for some fixed sufficiently small $\mu$ which we specify later, in the proof of Proposition 3.16. Let $\psi_{\mu}: \mathfrak{g l}_{P^{\prime}} \rightarrow \mathfrak{g}_{P^{\prime}}$ be the adjoint equivariant cut-off of the map $\psi$,

$$
\psi_{\mu}(g)=\rho_{\mu}(|\psi(g)|) \psi(g) \quad \text { for } g \in \mathfrak{g l}_{P^{\prime}}
$$

and denote the induced maps by $\psi, \psi_{\mu}: \Gamma\left(\left.\mathfrak{g l}_{P^{\prime}}\right|_{B}\right) \rightarrow \Gamma\left(\left.\mathfrak{g}_{P^{\prime}}\right|_{B}\right)$, respectively. Now define

$$
V_{q, \omega}^{\mu}(A)=\omega \otimes\left(\psi_{\mu} \circ \operatorname{Hol}_{q}(A)\right) \in \Omega_{+}^{2}\left(\mathfrak{g}_{P^{\prime}}\right)
$$

Then, taking $l>2$, the map $V_{q, \omega}^{\mu}$ extends to a smooth map of Hilbert manifolds (see [23])

$$
V_{q, \omega}^{\mu}: \mathcal{A}_{L_{l}^{2, \delta}}\left(P^{\prime}, \alpha^{\prime}\right) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P^{\prime}}\right)\right)
$$

For the reference smooth connection $A_{0}$ there are constants $K_{n}$, depending only on $q$, $A_{0}$ and the cut-off function $\rho_{\mu}$, such that the $n^{\text {th }}$ derivative

$$
\left.D^{n} V_{q, \omega}^{\mu}\right|_{A}: L_{l}^{2, \delta}\left(\bigwedge^{1}\left(\mathfrak{g}_{P^{\prime}}\right)\right)^{n} \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P^{\prime}}\right)\right)
$$

satisfies

$$
\left\|\left.D^{n} V_{q, \omega}^{\mu}\right|_{A}\left(a_{1}, \ldots, a_{n}\right)\right\|_{L_{l, A_{0}}^{2, \delta}} \leq K_{n}\|\omega\|_{C^{l}} \prod_{i=1}^{n}\left\|a_{i}\right\|_{L_{l, A_{0}}^{2, \delta}},
$$

which follows from Proposition 7 in [23] since $V_{q, \omega}^{\mu}(A)$ and $\left.D^{n} V_{q, \omega}^{\mu}\right|_{A}$ are compactly supported in $\operatorname{supp} \omega$, and $L_{l}^{2, \delta}$-norm and $L_{l}^{2}$-norm are equivalent on $\operatorname{supp} \omega$.
Let $\pi=\left(\left\{B_{v}, q_{\nu}, \omega_{\nu}, \varepsilon_{\nu}\right\}_{\nu=1}^{N}, \mu\right)$ be a finite collection consisting of
(1) a 4-ball $B_{v}$ in $X$, a submersion $q_{v}: S^{1} \times B_{v} \rightarrow X$,
(2) a self-dual 2-form $\omega_{\nu} \in \Omega_{+}^{2}(X)$ with $\operatorname{supp} \omega_{\nu} \subset B_{\nu}$,
(3) coefficients $\varepsilon_{\nu} \in \mathbb{R}$, and
(4) a cut-off parameter $\mu>0$.

Then we call $\pi$ a perturbation data and define a smooth map of Hilbert manifolds

$$
V_{\pi}: \mathcal{A}\left(P^{\prime}, \alpha^{\prime}\right) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P^{\prime}}\right)\right), \quad A \mapsto V_{\pi}(A)=\sum_{\nu=1}^{N} \varepsilon_{\nu} V_{q_{\nu}, \omega_{\nu}}^{\mu}(A) .
$$

The perturbed moduli space $\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)$ with perturbation data $\pi$ is defined to be

$$
\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)=\left\{A \in \mathcal{A}\left(P^{\prime}, \alpha^{\prime}\right) \mid F_{A}^{+}+V_{\pi}(A)=0\right\} / \mathcal{G}\left(P^{\prime}, \alpha^{\prime}\right)
$$

Now we have the following:
Proposition 3.16 Let $\mathcal{P}^{\prime}$ be a finite set of nontrivial adapted bundles ( $P^{\prime}, \alpha^{\prime}$ ) with $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0$ over a 4 -manifold $X$ with cylindrical ends. Suppose there is no reducible connection in the bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ and $\operatorname{ind}^{+}\left(P^{\prime}, \alpha^{\prime}\right)<0$ for all $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}^{\prime}$. Then there exists a perturbation data $\pi=\left(\left\{B_{v}, q_{v}, \omega_{v}, \varepsilon_{\nu}\right\}_{\nu=1}^{N}, \mu\right)$ such that

$$
\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing
$$

for all $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}^{\prime}$. If there is no reducible flat connection on the trivial bundle $\left(X \times \mathrm{SU}(2), \theta_{0}\right)$ except for the trivial flat connection $\theta$ then $\mathcal{M}^{\pi}\left(X \times \operatorname{SU}(2), \theta_{0}\right)=\{[\theta]\}$.

Proof The proof is essentially the same as that of Proposition 2.6 in [7]. Since the second homology $H_{A}^{2}$ of the Atiyah-Hitchin-Singer complex is finite-dimensional for each flat connection $A$, we can take a finite number of mutually disjoint embeddings $q_{\nu}: S^{1} \times B_{v} \rightarrow X$ and self-dual 2-forms $\omega_{\nu}$ with support inside 4-balls $B_{v}$ such that $\left\{\omega_{\nu} \otimes\left(\psi \circ \operatorname{Hol}_{q_{\nu}}(A)\right)\right\}_{\nu}$ span the space $H_{A}^{2}$ for each irreducible flat connection $A$, where $\psi: \mathfrak{g l}_{P^{\prime}} \rightarrow \mathfrak{s u}_{P^{\prime}}$ is the adjoint equivariant map defined above. Since the space of all flat connections is compact and the trivial flat connection is isolated for $b_{1}(X)=0$ and $b_{2}^{+}(X)=0$, the irreducible part $V$ is compact. Then we can take a finite collection $\left\{\omega_{v} \otimes\left(\psi \circ \operatorname{Hol}_{q_{v}}(A)\right)\right\}_{\nu}$ to span $H_{A}^{2}$ for all irreducible $A$, so that there is no solution on an open neighborhood $U$ of $V$ in $\mathcal{B}(P, \alpha)$. Note that the Uhlenbeck compactness [35] holds with small holonomy perturbation due to the fact that (i) there exist constants $\varepsilon_{0}>0$ and $C>0$ such that for any sufficiently small ball $B_{x}$ centered at each point $x$ such that $\left\|F_{A}\right\|_{L^{2}\left(B_{x}\right)}<\varepsilon_{0}$, there exists a connection matrix $\tilde{A}$ with respect to a trivialization such that $d^{*} \tilde{A}=0$ and

$$
\|\widetilde{A}\|_{L_{1}^{2}\left(B_{x}\right)} \leq C\left\|F_{A}\right\|_{L^{2}\left(B_{x}\right)},
$$

and (ii) for each $s \geq 2$, there exists a polynomial $R_{s}(Z, W) \in \mathbb{R}[Z, W]$ and an interior domain $x \in D_{s} \Subset B_{x}$ such that if $\|\widetilde{A}\|_{L_{1}^{2}\left(B_{x}\right)}<\varepsilon_{1}$ and $|\varepsilon|:=\max \left\{\left|\varepsilon_{\nu}\right|\right\}$ then

$$
\|\tilde{A}\|_{L_{s}^{2}\left(D_{s}\right)} \leq R_{s}\left(\varepsilon_{1},|\varepsilon|\right)
$$

Now take $\mu>0$ to be
$\mu=\frac{1}{2} \min \left\{\min _{x \in B_{v}}\left|\psi \circ \operatorname{Hol}_{q_{v, x}}(A)\right| \mid v \in\{1, \ldots, N\},[A] \in \mathcal{M}^{*}\left(P^{\prime}, \alpha^{\prime}\right),\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}^{\prime}\right\}$.
Note also that the trivial flat connection is the isolated solution during the holonomy perturbation. Then we see that there is no solution outside $U$ for sufficiently small perturbations. Now by definition of $\mu$ we have $\psi_{\mu} \circ \operatorname{Hol}_{q_{v}}(A)=\psi \circ \operatorname{Hol}_{q_{v}}(A)$ for $[A] \in \mathcal{M}^{*}\left(P^{\prime}, \alpha^{\prime}\right)$ and the perturbation $V_{\pi}$ has the required properties.

Then, by using Propositions 3.15 and 3.16, we obtain:
Proposition 3.17 Let $X$ be a 4 -manifold with cylindrical ends $\mathbb{R}_{+} \times Y_{i}$ for $i \in I$. Let $(P, \alpha)$ be an adapted $\operatorname{SU}(2)$-bundle over $X$ with

$$
0<c_{2}(P, \alpha)=\epsilon=\min \left\{\tau\left(Y_{i}, \alpha_{i}\right) \mid i \in I\right\} \leq \frac{1}{2} .
$$

Let $\mathcal{P}^{\prime}$ be the finite set of all possible limiting adapted $\mathrm{SU}(2)$-bundles ( $P^{\prime}, \alpha^{\prime}$ ) over $X$ which come from $(P, \alpha)$ satisfying

$$
\begin{equation*}
c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0 \tag{1}
\end{equation*}
$$

(2) $\operatorname{ind}^{+}\left(P^{\prime}, \alpha^{\prime}\right)<0$,
(3) there is no reducible instantons on $\left(P^{\prime}, \alpha^{\prime}\right)$, that is, $\mathcal{M}_{\text {red }}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$.

Then there exists a holonomy perturbation

$$
V_{\pi}: \mathcal{A}(P, \alpha) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right), \quad V_{\pi}(A)=\sum_{\nu=1}^{N} \rho_{\nu}(A) \varepsilon_{\nu} V_{q_{\nu}, \omega_{\nu}}^{\mu}(A)
$$

with perturbation data $\pi=\left(\left\{B_{v}, q_{\nu}, \omega_{\nu}, \varepsilon_{\nu}\right\}_{\nu=1, \ldots, N}, \mu\right)$ satisfying $q_{\nu}\left(S^{1} \times B_{\nu}\right) \cap$ $\left(\mathbb{R}_{+} \times Y_{i}\right)=\varnothing$ for all $i \in I, v \in\{1, \ldots, N\}$ and $\mathcal{G}(P, \alpha)$-invariant smooth functions

$$
\rho_{\nu}: \mathcal{A}(P, \alpha) \rightarrow \mathbb{R} \quad \text { for } v \in\{1, \ldots, N\}
$$

such that $\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$ for all adapted bundle $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}^{\prime}$ and if $(X \times \operatorname{SU}(2), \theta)$ admits no nontrivial reducible flat connection then $\mathcal{M}^{\pi}(X \times \operatorname{SU}(2), \theta)=\{[\theta]\}$.

Proof By Proposition 3.16, we can take a perturbation $\pi=\left(\left\{B_{\nu}, q_{\nu}, \omega_{\nu}, \varepsilon_{\nu}\right\}, \mu\right)$ so that $\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$ for all $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}^{\prime}$ and if $(X \times \operatorname{SU}(2), \theta)$ admits no reducible flat connection then $\mathcal{M}^{\pi}(X \times \operatorname{SU}(2), \theta)=\{[\theta]\}$. Here, by taking $B_{v}$ sufficiently small and $q_{x}: S^{1} \times\{x\} \rightarrow X$ in general position, we may assume $q_{v}\left(S^{1} \times B_{v}\right)$ are inside $W=X-\coprod_{i \in I}\left(\mathbb{R}_{+} \times Y_{i}\right)$ and they are all disjoint and take $\lambda>0$ to be less than a half of the distances between them. Then we can take a $\lambda$-neighborhood $U_{v}$ of the image $q_{v}\left(S^{1} \times B_{v}\right)$ and set a $\mathcal{G}(P, \alpha)$-invariant function

$$
E_{\nu}(A)=\frac{1}{8 \pi^{2}} \int_{U_{v}}\left|F_{A}(y)\right|^{2} \operatorname{vol}_{X}(y)
$$

to define a $\mathcal{G}(P, \alpha)$-invariant smooth map $\rho_{\nu}: \mathcal{A}(P, \alpha) \rightarrow \mathbb{R}$ by composing with a smooth cut-off function. Then the assertion follows from Propositions 3.16 and 3.15.

### 3.8 Taubes' gluing instantons

In our discussion, it is crucial to construct an end of the instanton moduli space and in particular the moduli space need to be nonempty. We use a result of Taubes concerning gluing of instantons.

Let $\left(P_{k}, \alpha_{k}\right)$ for $k=1,2$ be an adapted $\mathrm{SU}(2)$-bundle over a $4-$ manifold $X_{k}$ with cylindrical ends $\mathbb{R}_{+} \times Y_{k i}$ indexed by $i \in I_{k}$ for a finite set $I_{k}$ containing 0 and with an identification $Y_{10}=Y=-Y_{20}$ for the $i=0^{\text {th }}$ component, and a fixed bundle isomorphism $h:\left.\left.P_{1}\right|_{\mathbb{R}_{+} \times Y_{10}} \rightarrow P_{2}\right|_{\mathbb{R}_{+} \times Y_{20}}$ such that $\alpha_{10}=h^{*} \alpha_{20}$. Let $A_{k}$ be an
instanton on $\left(P_{k}, \alpha_{k}\right)$. For a fixed parameter $T>0$, we defined an adapted $\mathrm{SU}(2)-$ bundle $\left(P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}\right)$ over the glued 4-manifold $X_{1} \#_{(T)} X_{2}$ in Definition 3.10. If $X_{1}=X=W \cup \coprod_{i}\left(\mathbb{R}_{+} \times Y_{1 i}\right)$ and $X_{2}=\mathbb{R} \times Y, \alpha_{2}=\left\{\alpha_{20}, \alpha_{21}\right\}$ then $X_{1} \#_{(T)} X_{2}=$ $X \#_{(T)}(\mathbb{R} \times Y)$ is diffeomorphic to $X_{1}=X$. Now we identify $Q_{11}=Q_{21}, \alpha_{11}=\alpha_{21}$ and $\mathbb{R} \times Q_{21} \cong P_{2}$ using the parallel translation, $P_{1} \#_{(T)} P_{2}$ is isomorphic to $P_{1}$ and $\alpha_{1} \# \alpha_{2}=\left(\alpha_{1}-\left\{\alpha_{10}\right\}\right) \cup\left\{\alpha_{21}\right\}$. Therefore, we have an isomorphism as adapted bundles

$$
\left(P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}\right) \cong\left(P_{1},\left(\alpha_{1}-\left\{\alpha_{10}\right\}\right) \cup\left\{\alpha_{21}\right\}\right) .
$$

Fix a Riemannian metric on $X_{k}$ for $k=1,2$ with product ends. Let $\mathcal{M}^{\prime}\left(P_{2}, \alpha_{2}\right)$ be the (translation-)reduced moduli space, that is, the moduli space of instantons $A$ on the adapted $\mathrm{SU}(2)$-bundle $\left(P_{2}, \alpha_{2}\right)$ over $\mathbb{R} \times Y$ with the center of mass zero,

$$
\int_{-\infty}^{\infty} t\left|F_{A}\right|^{2} \operatorname{vol}_{\mathbb{R} \times Y}=0
$$

so that $\mathcal{M}\left(P_{2}, \alpha_{2}\right)=\mathbb{R} \times \mathcal{M}^{\prime}\left(P_{2}, \alpha_{2}\right)$ under the identification $(t, A) \mapsto c_{t}^{*} A$ using translation $c_{t}$ by $t$. We denote by $\Gamma_{\alpha_{10}}$ the stabilizer of $\alpha_{10}$ in the gauge transformation group of $\left.P_{k}\right|_{Y_{k 0}}$, and let $\widetilde{\mathcal{M}}\left(P_{k}, \alpha_{k}\right)$ be the framed moduli space of instantons on $\left(P_{k}, \alpha_{k}\right)$ with respect to the stabilizer $\Gamma_{\alpha_{10}}$, so that $\widetilde{\mathcal{M}}\left(P_{k}, \alpha_{k}\right) / \Gamma_{\alpha_{10}} \cong \mathcal{M}\left(P_{k}, \alpha_{k}\right)$. Then Taubes' gluing result is the following:

Theorem 3.18 (see [8, Section 4.4]) Let $A_{k}$ be an instanton on ( $P_{k}, \alpha_{k}$ ) for $k=1,2$, $N_{k} \subset \mathcal{M}\left(P_{k}, \alpha_{k}\right)$ a precompact neighborhood around $\left[A_{k}\right]$ whose closure consists of irreducible and regular points and $\widetilde{N}_{k}=p_{k}^{-1}\left(N_{k}\right)$ the inverse image of the projection $p_{k}: \widetilde{\mathcal{M}}\left(P_{k}, \alpha_{k}\right) \rightarrow \mathcal{M}\left(P_{k}, \alpha_{k}\right)=\widetilde{\mathcal{M}}\left(P_{k}, \alpha_{k}\right) / \Gamma_{\alpha_{10}}$. Then there exists a map

$$
\tau_{T}: E=\tilde{N}_{1} \times_{\Gamma_{\alpha_{10}}} \tilde{N}_{2} \rightarrow \mathcal{M}\left(P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}\right)
$$

which is a diffeomorphism onto a neighborhood of the moduli space of instantons on the adapted bundle ( $P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}$ ) over the gluing $X_{1} \#_{(T)} X_{2}$ for sufficiently large $T>0$.

In particular, if $X_{2}=\mathbb{R} \times Y_{2}$, then $\left(P_{1} \#_{(T)} P_{2}, \alpha_{1} \# \alpha_{2}\right) \cong\left(P_{1},\left(\alpha_{1}-\left\{\alpha_{10}\right\}\right) \cup\left\{\alpha_{21}\right\}\right)$. Let $N_{2}^{\prime} \subset \mathcal{M}^{\prime}\left(P_{2}, \alpha_{2}\right)$ be a precompact neighborhood around $\left[A_{2}\right.$ ] whose closure consists of irreducible and regular points and $\widetilde{N}_{2}^{\prime}=p_{2}^{-1}\left(N_{2}^{\prime}\right)$ be the inverse image of the projection $p_{2}$ : $\widetilde{\mathcal{M}}^{\prime}\left(P_{2}, \alpha_{2}\right) \rightarrow \mathcal{M}^{\prime}\left(P_{2}, \alpha_{2}\right)=\widetilde{\mathcal{M}}^{\prime}\left(P_{2}, \alpha_{2}\right) / \Gamma_{\alpha_{10}}$, and suppose $N_{1}$ is isolated and regular in $\mathcal{M}\left(P_{1}, \alpha_{1}\right)$; then

$$
\tau: E=\tilde{N}_{1} \times_{\Gamma_{\alpha_{10}}} \tilde{N}_{2}^{\prime} \times(T, \infty) \rightarrow \mathcal{M}\left(P_{1},\left(\alpha_{1}-\left\{\alpha_{10}\right\}\right) \cup\left\{\alpha_{21}\right\}\right)
$$

gives a diffeomorphism onto an end of the moduli space for sufficiently large $T>0$.

Proof This is now a standard result and follows by taking the function spaces with $l>2$,

$$
U=L_{l-1}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P_{\#(T)}}\right)\right), \quad V=L_{l}^{2, \delta}\left(\left(\bigwedge^{0} \oplus \bigwedge^{1}\right)\left(\mathfrak{g}_{P_{\#(T)}}\right)\right)
$$

in the proof of Theorem 4.17 in [8] and an argument for gluing reducible instantons [8, Section 4.4.1; 9, Theorem 7.2.62].

We apply Theorem 3.18 to show:
Theorem 3.19 Suppose $l>2$. Let $X$ be a Riemannian 4-manifold with cylindrical ends $\mathbb{R}_{+} \times Y_{i}$ for $i \in I$ having the following properties:
(1) $b_{1}(X)=0$ and $b_{2}^{+}(X)=0$,
(2) $i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(X ; \mathbb{Z})$ is surjective, where $i: Y=\coprod_{i \in I} Y_{i} \hookrightarrow X$ is the inclusion,
(3) all $Y_{i}$ are rational homology 3-spheres and $Y_{1}=S^{3} / G_{1}$ is positive.

Let $(P, \alpha)$ be the adapted bundle obtained by gluing of the trivial bundle $\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ over $X$ and the adapted bundle $(Q, \beta)$ over $\mathbb{R} \times Y_{1}$ of $c_{2}(Q, \beta)=1 / m$ associated with the positive subgroup $G_{1}$ of $\mathrm{SO}(4)=\mathrm{Sp}(1) \times_{\{ \pm 1\}} \mathrm{Sp}(1)$ with $\beta_{-}=\theta$ and $\beta_{+}=\rho_{1}$ along $Y_{1}$, where $\rho_{1}$ corresponds to the inclusion $\rho_{1}: G_{1} \hookrightarrow \operatorname{Sp}(1)$. Let

$$
V_{\pi}: \mathcal{A}(P, \alpha) \rightarrow L_{l-1}^{2, \delta}\left(\wedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)
$$

be a holonomy perturbation with perturbation data $\pi=\left(\left\{B_{v}, q_{\nu}, \omega_{\nu}, \varepsilon_{\nu}\right\}, \mu\right)$ such that the perturbed moduli space $\mathcal{M}^{\pi}\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ consists only of the gauge equivalence class [ $\theta$ ] of the trivial flat connection $\theta$ on $X \times \mathrm{SU}(2)$. Then the perturbed moduli space $\mathcal{M}^{\pi}(P, \alpha)$ of the bundle $(P, \alpha)$ has at least one end component.

Proof Note that the trivial flat connection $\theta$ over rational homology 3-sphere $Y_{i}$ is non-degenerate, $H^{1}\left(Y_{i}, \mathrm{ad}_{\theta}\right)=\{0\}$. Since $H_{\theta}^{1}=H^{1}(X ; \mathbb{R}) \otimes \mathfrak{g}=\{0\}$ and $H_{\theta}^{2}=H_{+}^{2}(X ; \mathbb{R}) \otimes \mathfrak{g}=\{0\}$, the moduli space $\mathcal{M}\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ has an isolated point $[\theta]$ corresponding to the gauge equivalence class of the trivial flat connection $\theta$ on $X \times \mathrm{SU}(2)$ and $[\theta]$ is a regular point. Now the set of all reducible instantons $\mathcal{M}_{\text {red }}\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ has a one-to-one correspondence with the set

$$
\left\{\chi \in \operatorname{Hom}\left(H_{1}(X ; \mathbb{Z}), U(1)\right) \mid \chi \circ\left(i_{j}\right)_{*}=0 \text { for } j \in I\right\} / \chi \sim \bar{\chi},
$$

where $i_{j}: Y_{j} \hookrightarrow X$ is the inclusion. Since $i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(X ; \mathbb{Z})$ is surjective we see that $\mathcal{M}_{\text {red }}\left(X \times \operatorname{SU}(2), \theta_{0}\right)=\{[\theta]\}$. Note that the virtual dimension of the moduli
space $\mathcal{M}\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ is

$$
\operatorname{vir} \operatorname{dim} \mathcal{M}\left(X \times \mathrm{SU}(2), \theta_{0}\right)=-3\left(1-b_{1}(X)+b_{2}^{+}(X)\right)=-3<0
$$

Let $\pi=\left(\left\{B_{v}, q_{v}, \omega_{\nu}, \varepsilon_{v}\right\}_{v=1}^{N}, \mu\right)$ be a perturbation data such that the perturbed moduli space $\mathcal{M}^{\pi}\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ with respect to the holonomy perturbation

$$
V_{\pi}: \mathcal{A}(P, \alpha) \rightarrow L_{l}^{2, \delta}\left(\bigwedge_{+}^{2}\left(\mathfrak{g}_{P}\right)\right)
$$

consists only of the gauge equivalence class $[\theta]$ of trivial flat connection $\theta$. Let us denote $\mathcal{A}_{L_{l}^{2, \delta}}(P, \alpha)$ simply by $\mathcal{A}$, and so on. Let $\operatorname{Hol}_{q}(A) \in L_{l}^{2}\left(\left.\mathfrak{g l}_{P}\right|_{B}\right)$ be the holonomy function over $B$ of an $L_{l}^{2, \delta}$-connection $A$ along the family of loops $q: S^{1} \times B \rightarrow X$. Since $L_{l, \text { loc }}^{2} \subset C^{0}, \operatorname{Hol}_{q}(A)$ is continuous on $B$, so that we have definite values $\left(\operatorname{Hol}_{q}(A)\right)(x)$ for each $x \in B$, which we denote by $\operatorname{Hol}_{q_{x}}(A)$. Let $f_{q}: \mathcal{A} \rightarrow \mathbb{R}$ be the $\mathcal{G}$-invariant continuous function

$$
f_{q}(A)=\max _{x \in B}\left|\psi \circ \operatorname{Hol}_{q_{x}}(A)\right| .
$$

We denote the induced map $f_{q}: \mathcal{B}=\mathcal{A} / \mathcal{G} \rightarrow \mathbb{R}$ by the same symbol by abuse of notation. Let $U$ be an open set in $\mathcal{B}$ defined by

$$
U=\bigcap_{\nu=1}^{N} f_{q_{\nu}}^{-1}((-\infty, \mu))
$$

Let $\widetilde{\mathcal{B}}$ be the space of gauge equivalence classes of framed connections on $(P, \alpha)$ with respect to $\Gamma_{\alpha_{1}}=\Gamma_{\theta}$ and $p: \widetilde{\mathcal{B}} \rightarrow \mathcal{B}=\widetilde{\mathcal{B}} / \Gamma_{\theta}$ be the basepoint fibration and take the intersection $\tilde{N}_{1}$ of the open set $\tilde{U}=p^{-1}(U)$ in $\tilde{\mathcal{B}}$, and let $\widetilde{\mathcal{M}}^{\pi}\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ be the perturbed framed moduli space.

Since $V_{\pi}(A)=0$ for $[A] \in \tilde{U}, \tilde{N}_{1}$ is equal to the intersection of $\tilde{U}$ and the unperturbed framed moduli space $\widetilde{\mathcal{M}}\left(X \times \mathrm{SU}(2), \theta_{0}\right)$ consisting only of the $\mathrm{SU}(2)$-conjugate orbit of the trivial flat connection $\theta$, the fiber $p^{-1}([\theta])$ is a single point $\{[\theta]\}$ and hence

$$
\tilde{N}_{1}=\tilde{U} \cap \widetilde{\mathcal{M}}^{\pi}\left(X \times \mathrm{SU}(2), \theta_{0}\right)=\tilde{U} \cap \tilde{\mathcal{M}}\left(X \times \operatorname{SU}(2), \theta_{0}\right)=\{[\theta]\} .
$$

On the other hand, the moduli space $\mathcal{M}(Q, \beta)$ of the adapted bundle $(Q, \beta)$ over $\mathbb{R} \times Y_{1}$ of $c_{2}(Q, \beta)=1 / m$ associated with the positive subgroup $G_{1}$ with $\beta_{-}=\theta$ and $\beta_{+}=\rho$ which corresponds to the standard representation $\rho: G \hookrightarrow \mathrm{SU}(2)$ is diffeomorphic to the moduli space $\mathcal{M}(\widetilde{Q})^{G_{1}}$ of $G_{1}$-invariant instantons on a $G_{1}$-equivariant $\mathrm{SU}(2)$ bundle $\widetilde{Q}$ over $S^{4}$ and hence is diffeomorphic to $\mathbb{R}$ and the corresponding reduced moduli space is a point, $\mathcal{M}^{\prime}(Q, \beta)=\{\mathrm{pt}\}$. Note that all instantons on $(Q, \beta)$ are
irreducible. The space $\mathcal{M}(Q, \beta)$ is regular; see Proposition 3.5. Since the point in $\mathcal{M}^{\prime}(Q, \beta)$ is irreducible, its framed moduli space $\widetilde{\mathcal{M}}^{\prime}(Q, \beta)$ is $\mathrm{SU}(2)$, so that we may take its precompact neighborhood $\widetilde{N}_{2}^{\prime}$ to be $\widetilde{\mathcal{M}}^{\prime}(Q, \beta)$ itself. Now the stabilizer of the flat connection $\theta$ is $\Gamma_{\theta}=\operatorname{SU}(2)$. Then, by Theorem 4.17 in [8] and the argument for the reducible case [8, Section 4.4.1], the Taubes' gluing map
$\tau: E=\tilde{N}_{1} \times_{\Gamma_{\theta}} \tilde{N}_{2}^{\prime} \times(T, \infty) \rightarrow U \cap \mathcal{M}\left((X \times \operatorname{SU}(2)) \# Q, \theta_{0} \# \beta\right)=U \cap \mathcal{M}^{\pi}(P, \alpha)$ gives a diffeomorphism onto an end of the perturbed moduli space $\mathcal{M}^{\pi}(P, \alpha)$ of $\pi-$ instantons contained in $U$ for a sufficiently long "neck" $T \gg 0$. Then the assertion follows from the diffeomorphism

$$
\begin{aligned}
E & =\tilde{N}_{1} \times \Gamma_{\theta} \tilde{N}_{2}^{\prime} \times(T, \infty)=\{[\theta]\} \times_{\Gamma_{\theta}} \widetilde{\mathcal{M}}^{\prime}(Q, \beta) \times(T, \infty) \\
& \cong\{[\theta]\} \times \widetilde{\mathcal{M}}^{\prime}(Q, \beta) / \Gamma_{\theta} \times(T, \infty) \\
& \cong\{[\theta]\} \times \operatorname{SU}(2) / \operatorname{SU}(2) \times(T, \infty) \cong(T, \infty) .
\end{aligned}
$$

## 4 Main theorem

In this section, we state and prove Theorem 4.1 by using the preliminary result of Donaldson theory discussed in the previous section.

### 4.1 Statement of the main theorem

Our theorem is stated with condition only on the homology groups without referring to the fundamental groups itself, which is our major deviation from a theorem in [16].

Theorem 4.1 Let $X$ be an oriented smooth 4-manifold with cylindrical ends $\mathbb{R}_{+} \times Y_{i}$ for $i \in\{1, \ldots, s+t\}$, where $Y_{i}$ for $i \in\{1, \ldots, s\}$ are spherical space forms $Y_{i} \cong S^{3} / G_{i}$ and $Y_{s+k}=\Sigma_{k}$ for $k \in\{1, \ldots, t\}$ are rational homology 3-spheres. Suppose that $X$ satisfies the following conditions:
(1) $b_{1}(X)=0, b_{2}^{+}(X)=0$.
(2) $\operatorname{Cok}\left(H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(X ; \mathbb{Z})\right)=\{0\}$ and $Y=\coprod_{i=1}^{S+t} Y_{i}$.

Set $m=\max \left\{\left|G_{i}\right| \mid i \in\{1, \ldots, s\}\right\}$. Then there exists a positive constant $N(\Sigma)>0$, depending only on $\Sigma=\coprod_{k=1}^{t} \Sigma_{k}$, such that if $m>N(\Sigma)$ the following property holds: Let $Y_{1}$ be a positive spherical space form satisfying the following conditions:
(1) $\left|G_{1}\right|=m$.
(2) If $G_{1}$ is cyclic, then we assume that

$$
\kappa=\#\left\{e \in H^{2}(X) \left\lvert\, e^{2}=-\frac{1}{\left|G_{1}\right|}\right., i_{1}^{*} e= \pm e\left(L_{\rho}\right), i_{j}^{*} e=0 \text { for } j \neq 1\right\} /\{ \pm 1\}
$$

is even, where $i_{j}: Y_{j} \hookrightarrow X$ is the inclusion and $L_{\rho}=S^{3} \times{ }_{G_{1}} S^{1} \rightarrow Y_{1}$ is the $S^{1}$-bundle associated with the inclusion $\rho: G_{1} \hookrightarrow S^{1} \subset \mathrm{SU}(2)$.
(3) The intersection of the images of the two maps

$$
\begin{aligned}
& \operatorname{Hom}\left(H_{1}(X ; \mathbb{Z}), S^{1}\right) \rightarrow \operatorname{Hom}\left(G_{1}, S^{1}\right), \\
& \operatorname{Hom}\left(G_{1} / N_{1},\{ \pm 1\}\right) \rightarrow \operatorname{Hom}\left(G_{1}, S^{1}\right)
\end{aligned}
$$

is $\{1\}$, where $N_{1}$ is the normal subgroup of $G_{1}$ generated by elements $g \in G_{1}$ of ord $g \neq 4$.

Then there exists a negative spherical space form $Y_{i}$ with $i \neq 1$ such that the following holds:
(1) $\left|G_{i}\right|=m$ and there exists a representation

$$
\chi: \pi_{1}\left(X, x_{0}\right) \rightarrow \mathrm{SU}(2)
$$

such that the induced map $\chi \circ\left(i_{j}\right)_{*}: G_{j} \rightarrow \mathrm{SU}(2)$ is conjugate to the inclusion homomorphism $G_{j} \hookrightarrow \mathrm{SU}(2)$ if $j \in\{1, i\}$ and is the trivial homomorphism $G_{j} \rightarrow\{1\}$ for any $j \notin\{1, i\}$, where $\left(i_{j}\right)_{*}: \pi_{1}\left(Y_{j}, y_{j}\right) \rightarrow \pi_{1}\left(X, x_{0}\right)$ is induced by the inclusion $i_{j}: Y_{j} \hookrightarrow X$ and a path from $y_{j} \in Y_{j}$ to $x_{0} \in X$.
(2) If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic, then $G_{i}=\mathbb{Z}_{m}$ and there exists a character

$$
\chi: H_{1}(X ; \mathbb{Z}) \rightarrow U(1)
$$

such that the induced map $\chi \circ\left(i_{j}\right)_{*}: G_{j} \rightarrow U(1)$ is the inclusion $\mathbb{Z}_{m} \hookrightarrow U(1)$ up to complex conjugation for $j \in\{1, i\}$ and is trivial $G_{j} \rightarrow\{1\}$ for $j \notin\{1, i\}$, where $\left(i_{j}\right)_{*}: H_{1}\left(Y_{j} ; \mathbb{Z}\right) \rightarrow H_{1}(X ; \mathbb{Z})$ is induced by the inclusion $i_{j}: Y_{j} \hookrightarrow X$.

Remark 4.2 The condition (3) for the group $G_{1}$ in Theorem 4.1 is automatically satisfied if $G_{1}$ is not isomorphic to $\mathbb{Z}_{4}$ or to any binary dihedral groups [16, Lemma 2.1; 14, Section 6].

Remark 4.3 The author does not know whether the character $\chi \circ\left(i_{j}\right)_{*}: G_{j} \rightarrow U(1)$ for $j \in\{1, i\}$ in the statement of Theorem 4.1 is equal to the inclusion $G_{j} \subset U(1)$ itself or its complex conjugate.

Proof of Theorem 1.2 The lens space $L(a, b)$ is a special case of the spherical space form $S^{3} / G$ for $G=\mathbb{Z}_{a}$ and, in particular, $L(m, 1)$ (resp. $L(m,-1)$ is the positive (resp. negative) spherical space form as in Remark 3.8. Then $m \neq 4$ implies $G_{1} / N_{1}=\{1\}$ in the statement of Theorem 4.1. By the assumption that $\kappa=0$ is even, the assertion follows from Theorem 4.1.

Example 4.4 Let $Y=L(m, 1)$ and $(K,-m)$ be the trivial knot $K$ in $S^{3}$ with framing $-m$, so that the $(-m)-$ Dehn surgery along $K$ is $Y=\chi_{-m}(K)$, and $W=$ $B^{4} \cup\left(D^{2} \times D^{2}\right)$ be the compact oriented 4-manifold obtained by attaching 2-handle $D^{2} \times D^{2}$ along $K$ with framing $-m$. Then $W$ is a simply connected negativedefinite 4-manifold such that $i_{*}: H_{1}(Y ; \mathbb{Z})=\mathbb{Z}_{m} \rightarrow H_{1}(W ; \mathbb{Z})=\{0\}$ is surjective. On the other hand, $H_{2}(W ; \mathbb{Z})$ is generated by the 2 -sphere $S$ obtained by gluing a properly embedded disk in $B^{4}$ with boundary $K$ and the core of the 2 -handle $\{0\} \times D^{2} \subset D^{2} \times D^{2}$. Then, by taking the disk $D$ in $D^{2} \times D^{2}$ with boundary $\partial D=\mu$ the meridian loop of $K$, the rational intersection pairing is $D \cdot D=-1 / m$ and we have

$$
\begin{aligned}
\kappa & =\#\left\{a D \in H_{2}(W, Y ; \mathbb{Z}) \mid(a D) \bullet(a D)=-1 / m, \partial_{*}(a D)= \pm \mu\right\} /\{ \pm 1\} \\
& =\#\left\{a \in \mathbb{Z} \mid a^{2}=1, a \equiv \pm 1(\bmod m)\right\} /\{ \pm 1\}=1 .
\end{aligned}
$$

Since $\kappa$ is odd, we cannot apply Theorem 4.1.
Example 4.5 Let $Y=L(m,-1)=L(m, m-1)$ and $(L, \vec{m})=\bigcup_{i=1}^{m-1}\left(L_{i},-2\right)$ be a linear chain of $m-1$ components of trivial knots $L_{i}$ for $i \in\{1, \ldots, m-1\}$ of framing -2 and with linking number $\operatorname{lk}\left(L_{i}, L_{i+1}\right)=1$ for $i \in\{1, \ldots, m-2\}$, so that the corresponding Dehn surgery is $Y=\chi_{\vec{m}}(L)$. Now denote $V_{i}=D^{2} \times D^{2}$ and let $W=B^{4} \cup \coprod_{i=1}^{m-1} V_{i}$ be the compact oriented 4 -manifold obtained by attaching 2-handles $V_{i}$ along $L_{i}$ to the 4 -ball $B^{4}$ with framing -2 for $i \in\{1, \ldots, m-1\}$. Then $W$ is a simply connected negative-definite 4 -manifold such that $i_{*}: H_{1}(Y ; \mathbb{Z})=$ $\mathbb{Z}_{m} \rightarrow H_{1}(W ; \mathbb{Z})=0$ is surjective. On the other hand, $H_{2}(W ; \mathbb{Z})$ is generated by the 2 -spheres $S_{i}$ for $i \in\{1, \ldots, m-1\}$ obtained by gluing a properly embedded disk in $B^{4}$ with boundary $L_{i}$ and the core of the 2 -handle $\{0\} \times D^{2} \subset V_{i}=D^{2} \times D^{2}$. Then, by taking the disk $D_{i}$ in $V_{i}=D^{2} \times D^{2}$ with boundary $\partial D_{i}=\mu_{i}$ the meridian loop of $L_{i}$, the rational intersection pairing

$$
H_{2}(W, Y ; \mathbb{Z}) \times H_{2}(W, Y ; \mathbb{Z}) \rightarrow \mathbb{Q}
$$

is given by $\left(D_{i} \bullet D_{j}\right)=Q(W)^{-1}$, where $Q(W)=\left(S_{i} \bullet S_{j}\right)$ is the intersection matrix of $W$.

In particular, if $m=3$ for example, then

$$
\left(D_{i} \cdot D_{j}\right)=\frac{1}{3}\left(\begin{array}{ll}
-2 & -1 \\
-1 & -2
\end{array}\right)
$$

and we have

$$
\begin{aligned}
\kappa & =\#\left\{a D_{1}+b D_{2} \in H_{2}(W, Y ; \mathbb{Z}) \left\lvert\, \begin{array}{c}
\left(a D_{1}+b D_{2}\right)^{2}=-\frac{1}{3} \\
\partial_{*}\left(a D_{1}+b D_{2}\right)= \pm \mu_{1}
\end{array}\right.\right\} /\{ \pm 1\} \\
& =\#\left\{(a, b) \in \mathbb{Z}^{2} \mid 2\left(a^{2}+a b+b^{2}\right)=1, a+2 b \equiv \pm 1(\bmod m)\right\} /\{ \pm 1\}=0
\end{aligned}
$$

Here, we cannot apply Theorem 4.1 despite $\kappa$ being even because $L(m,-1)$ is not positive.

### 4.2 Proof of the main theorem

In this section we give a proof of Theorem 4.1. Let $(P, \alpha)$ be the adapted $\mathrm{SU}(2)$-bundle over $X$ obtained by gluing the trivial adapted bundle $\left(X \times \mathrm{SU}(2), \theta_{0}\right)$ over $X$ and the adapted bundle $(Q, \beta)$ over $\mathbb{R} \times Y_{1}$ defined in Definition 3.3 of $c_{2}(Q, \beta)=1 /\left|G_{1}\right|$ associated with the positive subgroup $G_{1}$ of $\mathrm{SO}(4)=\mathrm{SU}(2) \times_{\{ \pm 1\}} \mathrm{SU}(2)$ and with $\beta=\left\{\beta_{ \pm}\right\}$, where $\beta_{-}=\theta$ and $\beta_{+}=\alpha_{1}$ along $Y_{1}$, where $\alpha_{1}$ is the flat connection over $Y_{1}$ corresponding to the inclusion $\rho: G_{1} \hookrightarrow \mathrm{SU}(2)$ defined in Definition 3.7. Then $c_{2}(P, \alpha)=c_{2}(Q, \beta)=1 /\left|G_{1}\right|$. Note that $H^{1}(Y ; \operatorname{ad} \gamma)=\{0\}$ for any flat connection $\gamma$ over any spherical space form $Y$ and $H^{1}\left(Y_{0} ; \operatorname{ad} \theta\right)=\{0\}$ for the trivial flat connection $\theta$ over any $\mathbb{Q}$-homology 3-sphere $Y_{0}$. Fix a Riemannian metric $g$ on $X$ with product ends $\left.g\right|_{(0, \infty) \times Y_{i}}=d t^{2}+g_{Y_{i}}$. Let $\mathcal{M}(P, \alpha)$ be the moduli space of instantons on $P$,

$$
\mathcal{M}(P, \alpha)=\left\{A \in \mathcal{A}(P, \alpha) \mid F_{A}^{+}=0\right\} / \mathcal{G}(P, \alpha)
$$

The proof of Theorem 4.1 consists of a somewhat lengthy chain of lemmas. Here we sketch the main steps of the proof as follows:
(1) The moduli space $\mathcal{M}(P, \alpha)$ has virtual dimension one and the number of reducible instantons is even (Lemma 4.6).
(2) We construct a holonomy perturbation $\pi$ to obtain the perturbed moduli space $\mathcal{M}^{\pi}(P, \alpha)$ such that the irreducible part of the moduli spaces $\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)$ of the limiting flat bundles $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ with virtual dimension negative are all empty except for the trivial one, $\left(X \times \mathrm{SU}(2), \theta_{0}\right)$. Taubes' gluing construction works in our setting to see there is at least one end component of $\mathcal{M}^{\pi}(P, \alpha)$.
(3) Take a sequence $\left\{\left[A_{n}\right]\right\}$ in $\mathcal{M}^{\pi}(P, \alpha)$. Since the energy of $\pi$-instantons on $(P, \alpha)$ is nearly $1 / m$ no bubbling occurs and the series converges on $(P, \alpha)$ or chain
convergent to a $\pi$-instanton $\left[A^{\prime}\right]$ on some limiting flat adapted bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ and a genuine instanton $\left[B_{i}^{\prime}\right]$ with energy $1 / m$ on a limiting bundle ( $Q_{i}^{\prime}, \beta_{i}^{\prime}$ ) over $\mathbb{R} \times Y_{i}$ for one $i \in\{1, \ldots, s\}$ (sliding end).
(4) If $i \neq 1$ then we see $Y_{i}$ must be the negative spherical space form $Y_{i}=S^{3} / G_{i}$ with $\left|G_{i}\right|=m$ and the flat connection $\alpha_{i}=\theta_{i}$ changes in the limit to the one corresponding to the standard inclusion $\rho_{i}: G_{i} \hookrightarrow \mathrm{Sp}(1)$ and the virtual dimension of the moduli space of the limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ is $-\operatorname{dim} \Gamma_{\rho_{i}}$. In particular, if $G_{i}$ is cyclic then $-\operatorname{dim} \Gamma_{\rho_{i}}=-1$. On the other hand, if $i=1$ then $\alpha_{1}=\rho$ changes to the flat connection corresponding to the representation conjugate to $\varepsilon$ : $G_{1} \hookrightarrow\{ \pm 1\}$. In this case the virtual dimension of the moduli space of the limiting bundle ( $P^{\prime}, \alpha^{\prime}$ ) is -3 and so that $\varepsilon$ must be trivial by assumption and the perturbation $\pi$. Then we see that the limiting bundle must be trivial $\left(P^{\prime}, \alpha^{\prime}\right) \cong\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ (Lemmas 4.7, 4.8 and 4.9).
(5) Suppose there is no choice of the limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ except for the trivial one, $\left(X \times \mathrm{SU}(2), \theta_{0}\right)$. Then perturbing compact part of $\mathcal{M}^{\pi}(P, \alpha)$, we obtain a smooth 1 -manifold $\mathcal{M}^{\pi+\sigma}(P, \alpha)$ with even number of boundary points and with one end, which is impossible. Hence, there exists a nontrivial limiting flat bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ corresponding to the representation $\chi: \pi_{1}\left(X, x_{0}\right) \rightarrow \mathrm{Sp}(1)$ in the statement of Theorem 4.1. If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic then we use the proof by contradiction above to see there exists some limiting flat bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ with nontrivial reducible flat connection corresponding to the character $\chi: H_{1}(X ; \mathbb{Z}) \rightarrow S^{1}$ we are looking for (Lemmas 4.10 and 4.11).

Now we start the proof with the following:
Lemma 4.6 The moduli space $\mathcal{M}(P, \alpha)$ has virtual dimension one and the number $\kappa$ of reducible instantons is even.

Proof By Proposition 3.11(1), the virtual dimension of the moduli space $\mathcal{M}(P, \alpha)$ is equal to 1 . If $G_{1}$ is cyclic, then the inclusion $G_{1} \hookrightarrow \operatorname{Sp}(1)$ comes from the reducible one, $\rho: G_{1} \hookrightarrow S^{1}$, and all other flat connections $\alpha_{i}$ are the trivial one. Hence, by Proposition 3.1 there is a one-to-one correspondence between the set $\mathcal{M}_{\text {red }}(P, \alpha) \subset$ $\mathcal{M}(P, \alpha)$ of all reducible instantons on $(P, \alpha)$ and the set

$$
C(P, \alpha)=\left\{e \in H^{2}(X ; \mathbb{Z}) \left\lvert\, e^{2}=-\frac{1}{\left|G_{1}\right|}\right., \quad \begin{array}{l}
i_{1}^{*} e= \pm e\left(L_{\rho}\right), \\
i_{j}^{*} e=0 \text { for } j \neq 1
\end{array}\right\} /\{ \pm 1\},
$$

where $i_{j}: Y_{j} \hookrightarrow X$ is the inclusion and $L_{\rho}=S^{3} \times_{\rho} S^{1} \rightarrow Y_{1}$. On the other hand, if $G_{1} \subset \operatorname{Sp}(1)$ is not cyclic then there is no reducible instanton, $\mathcal{M}_{\text {red }}(P, \alpha)=\varnothing$.

Take any positive constant $N(\Sigma)>0$ satisfying $1 / N(\Sigma) \leq \min \left\{\tau\left(\Sigma_{k}, \theta\right) \mid k \in\{1, \ldots, t\}\right\}$. Then, for any $m=\left|G_{1}\right|=\max \left\{\left|G_{i}\right|\right\}>N(\Sigma)$ the adapted $\mathrm{SU}(2)$-bundle $(P, \alpha)$ over $X$ satisfies

$$
0<c_{2}(P, \alpha)=1 / m=\min \left\{\tau\left(Y_{i}, \alpha_{i}\right) \mid i \in\{1, \ldots, s+t\}\right\} \leq \frac{1}{2}
$$

Note that $\tau\left(Y_{s+k}, \alpha_{s+k}\right) \neq 1 / m$ for $k \in\{1, \ldots, t\}$. Let $\mathcal{R}(Y, \mathrm{SU}(2))$ be the space of all conjugacy classes of $\mathrm{SU}(2)$ representations of the fundamental group $\pi_{1}(Y)$. Now $Y_{i}=S^{3} / G_{i}$ are spherical space form for $i \in\{1, \ldots, s\}$ and hence $\# \mathcal{R}\left(Y_{i}, \mathrm{SU}(2)\right) \leq\left|G_{i}\right|$ is finite. Let $\mathcal{P}_{0}$ be the set of all adapted bundles $\left(P^{\prime}, \alpha^{\prime}\right)$ over $X$ satisfying
(1) $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0$,
(2) $\operatorname{ind}^{+}\left(P^{\prime}, \alpha^{\prime}\right)<0$,
(3) there are no reducible instantons on $\left(P^{\prime}, \alpha^{\prime}\right)$, that is, $\mathcal{M}_{\text {red }}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$, and
(4) $\alpha_{s+k}^{\prime}=\theta$ for $k \in\{1, \ldots, t\}$.

By (1), $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0$, the isomorphism class of adapted $\mathrm{SU}(2)-\operatorname{bundles}\left(P^{\prime}, \alpha^{\prime}\right) \in$ $\mathcal{P}_{0}$ with given flat limit $\alpha^{\prime}$ is unique. By (4), $\alpha_{s+k}^{\prime}=\theta$ for $k \in\{1, \ldots, t\}$ and $\# \mathcal{R}\left(Y_{i}, \mathrm{SU}(2)\right)$ is finite for $i \in\{1, \ldots, s\}$, so there are only finitely many possibilities for $\alpha_{i}^{\prime}$, so that the set $\mathcal{P}_{0}$ is finite. Then take a holonomy perturbation with perturbation data $\pi=\left(\left\{B_{\nu}, q_{\nu}, \omega_{\nu}, \varepsilon_{\nu}\right\}, \mu\right)$ as in Proposition 3.17 applied to the case $\mathcal{P}^{\prime}=\mathcal{P}_{0}$ and $\epsilon=1 / m$.

Let $\left\{\left[A_{n}\right]\right\}$ be a sequence in $\mathcal{M}^{\pi}(P, \alpha)$. Then Proposition 3.15 applied to the case $\epsilon=1 / m$ implies that, by taking gauge transformation if necessary, $A_{n}$ converges to a $\pi$-instanton $A^{\prime}$ on the original bundle $(P, \alpha)$ or converges to a $\pi$-instanton $A^{\prime}$ on a limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ over $X$ with an instanton $B_{i}^{\prime}$ formed on a limiting bundle $\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)$ over $\mathbb{R} \times Y_{i}$ for one $i \in\{1, \ldots, s\}$ satisfying

$$
c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0, \quad c_{2}\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)=\frac{1}{m}
$$

where

$$
\alpha_{j}^{\prime}=\alpha_{j} \quad \text { for } j \neq i, \quad \alpha_{i}^{\prime}=\beta_{i}^{\prime-}, \quad \beta_{i}^{\prime+}=\alpha_{i}
$$

Now if an adapted $\mathrm{SU}(2)$-bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ over $X$ is isomorphic to a limiting bundle after "bubbling" or "sliding end" of a sequence $\left\{\left[A_{n}\right]\right\}$ of instantons on a bundle $(P, \alpha)$ over $X$ with $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)<c_{2}(P, \alpha)$ then we denote $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$.

Then, by Proposition 3.11, we have vir $\operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)<0$, as follows:

Lemma 4.7 Let $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ be the limiting flat bundle. Then either one of the following holds:
(1) There exists $i \notin\{1, s+1, \ldots, s+t\}$ such that $Y_{i}$ must be negative and the flat connection $\alpha_{i}^{\prime}$ corresponds to a representation conjugate to the standard inclusion $\rho_{i}: G_{i} \hookrightarrow \operatorname{Sp}(1)$ and $\alpha_{k}^{\prime}=1$ for all $k \neq i$, and

$$
\operatorname{vir} \operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)=-\operatorname{dim} \Gamma_{\rho_{i}}
$$

In particular, if $G_{i}$ is cyclic then $\operatorname{vir} \operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)=-1<0$.
(2) The flat connection $\alpha_{1}^{\prime}$ corresponds to a representation conjugate to a representation $\varepsilon: G_{1} \rightarrow\{ \pm 1\}$ and $\varepsilon(g)=1$ for all $g \in G_{1}$ with ord $g \neq 4$ and $\alpha_{k}^{\prime}=1$ for $k \neq 1$, and in this case $\operatorname{vir} \operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)=-3<0$.

Proof Let $B_{i}^{\prime}$ be a limiting instanton formed on a limiting adapted $\mathrm{SU}(2)$-bundle $\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)$ over $\mathbb{R} \times S^{3} / G_{i}$ with

$$
c_{2}\left(Q_{i}^{\prime}, \beta_{i}^{\prime}\right)=1 /\left|G_{i}\right|=1 /\left|G_{1}\right|
$$

which corresponds to a $G_{i}$-invariant instanton $\widetilde{B}_{i}^{\prime}$ on a $G_{i}$-equivariant principal $\operatorname{SU}(2)$-bundle $\widetilde{Q}_{i}^{\prime}=\widetilde{Q}_{0}$ over $\mathbb{R} \times S^{3}$ associated with some $G_{i}$-action on $\widetilde{Q}_{0}$ given by ${\beta_{i}^{\prime}}^{ \pm}: G_{i} \rightarrow \operatorname{Sp}(1)$.

If $i \notin\{1, s+1, \ldots, s+t\}$ then, by definition of the adapted bundle $(P, \alpha)$ at $Y_{i}$, we have $\beta_{i}^{\prime+}=1$ and, by Proposition 3.9, $Y_{i}$ is negative,

$$
G_{i} \subset\{ \pm 1\} \times_{\{ \pm 1\}} \operatorname{Sp}(1) \subset \operatorname{Sp}(1) \times_{\{ \pm 1\}} \operatorname{Sp}(1)
$$

and $\beta_{i}^{\prime-}$ is conjugate to the inclusion $\rho_{i}: G_{i} \hookrightarrow \mathrm{Sp}(1)$. Then the limiting flat connection $\alpha_{i}^{\prime}$ on the $i^{\text {th }}$ component of the limiting adapted bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ is conjugate to $\beta_{i}^{\prime-}$ and hence to the inclusion $\rho_{i}$. Then, by Proposition 3.11(3), we have

$$
\operatorname{vir} \operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)=-\operatorname{dim} \Gamma_{\rho_{i}}
$$

In particular, if $G_{i}$ is cyclic then $\rho_{i}: G_{i}=\mathbb{Z}_{m} \hookrightarrow S^{1}$ for some $S^{1}$ subgroup of $\operatorname{Sp}(1)$ and $\Gamma_{\rho_{i}} \cong S^{1}$, so that the moduli space of the limiting bundle ( $P^{\prime}, \alpha^{\prime}$ ) has $\operatorname{vir} \operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)=-1<0$.

On the other hand, suppose $i=1$. Since $Y_{1}$ is positive,

$$
G_{1} \subset \operatorname{Sp}(1) \times_{\{ \pm 1\}}\{ \pm 1\} \subset \operatorname{Sp}(1) \times_{\{ \pm 1\}} \operatorname{Sp}(1)
$$

and, by definition of $(P, \alpha)$ to $Y_{1}$, we have $\beta_{1}^{\prime+}=\rho_{1}$. By Proposition 3.9, we have $\beta_{1}^{\prime-}=\varepsilon$ and $\rho_{1}$ is conjugate to $\varepsilon \rho_{1}$. Now evaluate $g \in G_{1}$ and take the trace; we get

$$
\operatorname{Tr} g=\operatorname{Tr} \rho_{1}(g)=\operatorname{Tr}\left(\varepsilon(g) \rho_{1}(g)\right)=\operatorname{Tr}(\varepsilon(g) g) \quad \text { for } g \in G_{1}
$$

Hence, $\varepsilon(g)=1$ for $g \in G_{1}$ with $\operatorname{Tr} g \neq 0$. This condition is equivalent to the condition that $\varepsilon(g)=1$ for ord $g \neq 4$. The virtual dimension of the moduli space of the limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ is $\operatorname{vir} \operatorname{dim} \mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)=-3<0$ by Proposition 3.11(2).

Lemma 4.8 If the limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ admits no reducible flat connection and ind ${ }^{+}\left(P^{\prime}, \alpha^{\prime}\right)<0$, then $\left(P^{\prime}, \alpha^{\prime}\right)$ belongs to $\mathcal{P}_{0}$.

Proof As we mentioned before the statement of Lemma 4.7, the limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right)$ satisfies $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0$. Suppose $\left(P^{\prime}, \alpha^{\prime}\right)$ admits no reducible flat connection, $\mathcal{M}_{\text {red }}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$, and the virtual dimension of the moduli space $\mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)$ is negative, ind $^{+}\left(P^{\prime}, \alpha^{\prime}\right)<0$. Since $c_{2}(P, \alpha)=1 / m$, Proposition 3.15 applied to the case $\epsilon=1 / \mathrm{m}$ implies that $\alpha_{s+k}^{\prime}=\theta$ for $Y_{s+k}=\Sigma_{k}$ for $k \in\{1, \ldots, t\}$ with $\tau\left(\Sigma_{k}, \theta\right) \geq 1 / N(\Sigma)>$ $1 / m=c_{2}(P, \alpha)$ and therefore $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}_{0}$.

Lemma 4.9 The representation $\varepsilon: G_{1} \rightarrow\{ \pm 1\}$ in Lemma 4.7(2) must be trivial and in this case $\left(P^{\prime}, \alpha^{\prime}\right) \cong\left(X \times \operatorname{SU}(2), \theta_{0}\right)$.

Proof By Lemma 4.7(2), the virtual dimension of the moduli space $\mathcal{M}\left(P^{\prime}, \alpha^{\prime}\right)$ is negative, $\operatorname{ind}^{+}\left(P^{\prime}, \alpha^{\prime}\right)<0$. Suppose $\left(P^{\prime}, \alpha^{\prime}\right)$ admits no reducible flat connection. Then, by Lemma 4.8, we see that $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}_{0}$. Since $c_{2}\left(P^{\prime}, \alpha^{\prime}\right)=0$ and $\alpha_{i}^{\prime} \in \mathcal{R}\left(Y_{i}, \mathrm{SU}(2)\right)$ with $\# \mathcal{R}\left(Y_{i}, \mathrm{SU}(2)\right)$ is finite for $i \in\{1, \ldots, s\}$ and $\alpha_{s+k}^{\prime}=\theta$ for $k \in\{1, \ldots, t\}$, we see $\mathcal{P}_{0}$ is a finite set so that, by Proposition 3.16, we have $\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$. Hence, there is no divergent sequence in $\mathcal{M}^{\pi}(P, \alpha)$ weakly convergent to a connection in $\mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)$, which contradicts the assumption that $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$. Therefore, $\left(P^{\prime}, \alpha^{\prime}\right)$ admits a reducible flat connection $A^{\prime}$ over $X$ with $\alpha_{1}^{\prime}=\varepsilon$. Then the corresponding holonomy representation $\operatorname{Hol}\left(A^{\prime}\right)$ of $A^{\prime}$ has a reduction to a circle subgroup $S^{1}$ of $\operatorname{Sp}(1)$ and satisfies $\operatorname{Hol}\left(A^{\prime}\right) \circ\left(i_{1}\right)_{*}=\varepsilon$, and we see that

$$
\begin{aligned}
& \varepsilon \in \operatorname{Im}\left(\operatorname{Hom}\left(H_{1}(X), S^{1}\right) \rightarrow \operatorname{Hom}\left(G_{1}, S^{1}\right)\right) \\
& \qquad \cap \operatorname{Im}\left(\operatorname{Hom}\left(G_{1} / N_{1},\{ \pm 1\}\right) \rightarrow \operatorname{Hom}\left(G_{1}, S^{1}\right)\right)=\{1\},
\end{aligned}
$$

where

$$
\left.N_{1}=\left\langle g \in G_{1}\right| \text { ord } g \neq 4\right\rangle
$$

and therefore $\varepsilon=1$. Now we know that $\operatorname{Hol}\left(A^{\prime}\right) \circ\left(i_{j}\right)_{*}=1$ for all $j \notin\{1, i\}$, so that $\operatorname{Hol}\left(A^{\prime}\right) \circ i_{*}=1$ for $i_{*}: H_{1}(Y) \rightarrow H_{1}(X)$. Since $i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(X ; \mathbb{Z})$ is
surjective, the homomorphism $H_{1}(X ; \mathbb{Z}) \rightarrow S^{1}$ induced by $\operatorname{Hol}\left(A^{\prime}\right)$ is trivial in all $H_{1}(X ; \mathbb{Z})$, so that the reducible flat connection $A^{\prime}$ is trivial and therefore $\left(P^{\prime}, \alpha^{\prime}\right) \cong$ $\left(X \times \operatorname{SU}(2), \theta_{0}\right)$.

Lemma 4.10 (1) There exists a sequence of instantons on $(P, \alpha)$ which weakly converges to some nontrivial flat $\mathrm{SU}(2)$-bundle $\left(P^{\prime}, \alpha^{\prime}\right)$, that is, $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$.
(2) If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic then there exists some limiting adapted flat $\mathrm{SU}(2)$-bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ which supports a nontrivial reducible flat connection.

Proof (1) By Theorem 3.19 applied to the case $\mathcal{P}^{\prime}=\mathcal{P}_{0}$ and $\epsilon=1 / m$, the perturbed moduli space $\mathcal{M}^{\pi}(P, \alpha)$ has one end component $\mathcal{N} \cong \mathbb{R}_{+}$admitting a divergent sequence weakly converging to the trivial flat connection $\theta$ on $\left(X \times \operatorname{SU}(2), \theta_{0}\right)$. Suppose there is no other limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ except for the trivial bundle $\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ then the complement $K=\mathcal{M}^{\pi}(P, \alpha) \backslash \mathcal{N}$ is compact. In fact, any sequence in $\mathcal{M}^{\pi}(P, \alpha)$ has a subsequence which converges to an instanton on $(P, \alpha)$ itself or weakly chain convergent to the trivial flat connection $\theta$ on $\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ up to gauge transformation, and for the latter case, the subsequence must have a subsequence contained in the component $\mathcal{N}$. Note that $b_{1}(X)=0$ and $b_{2}^{+}(X)=0$. Then, by Proposition 3.2, we take a perturbation $\sigma$ of $\mathcal{M}^{\pi}(P, \alpha)$ with support an open neighborhood of $K$ such that the perturbed moduli space $\mathcal{M}^{\pi+\sigma}(P, \alpha)$ is a smooth 1 -dimensional manifold with one end and even number $(=\kappa)$ of boundary points and this is impossible. Therefore, some ( $P^{\prime}, \alpha^{\prime}$ ) admits a nontrivial flat connection.
(2) Suppose all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic, so that $\Gamma_{\rho_{j}} \cong S^{1}$ and suppose that any limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ admits no nontrivial reducible flat connection over $X$. If ( $P^{\prime}, \alpha^{\prime}$ ) is not isomorphic to ( $\left.X \times \operatorname{SU}(2), \theta_{0}\right)$, then by assumption that there is no reducible on $\left(P^{\prime}, \alpha^{\prime}\right), \mathcal{M}_{\text {red }}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$, and

$$
\operatorname{ind}^{+}\left(P^{\prime}, \alpha^{\prime}\right)=-\operatorname{dim} \Gamma_{\rho_{j}}=-1<0,
$$

so, by Lemma 4.8, we have $\left(P^{\prime}, \alpha^{\prime}\right) \in \mathcal{P}_{0}$, and by Proposition $3.16, \mathcal{M}^{\pi}\left(P^{\prime}, \alpha^{\prime}\right)=\varnothing$. Hence, the limiting bundle ( $P^{\prime}, \alpha^{\prime}$ ) must be isomorphic to $\left(X \times \operatorname{SU}(2), \theta_{0}\right)$ and the perturbed moduli space $\mathcal{M}^{\pi}(P, \alpha)$ has at most one end. Then the rest of the argument goes as in (1) to get a contradiction, so that some limiting bundle ( $P^{\prime}, \alpha^{\prime}$ ) admits a reducible nontrivial flat connection.

Lemma 4.11 (1) There exists some limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ with a nontrivial flat connection which induces a representation $\chi: \pi_{1}\left(X, x_{0}\right) \rightarrow \operatorname{Sp}(1)$
such that $\chi \circ\left(i_{j}\right)_{*}$ is conjugate to the inclusion $G_{j} \hookrightarrow \operatorname{Sp}(1)$ for $j=1$, $i$ and is trivial otherwise.
(2) If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic, there is a limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ with a nontrivial reducible flat connection inducing a character $\chi: H_{1}(X ; \mathbb{Z}) \rightarrow$ $S^{1}$ such that $\chi \circ\left(i_{j}\right)_{*}$ is conjugate in $\operatorname{Sp}(1)$ to the inclusion $G_{j} \hookrightarrow S^{1}$ for $j=1, i$ and is trivial otherwise.

Proof (1) By Lemmas 4.10, 4.7 and 4.9, there exists a limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec$ $(P, \alpha)$ with a nontrivial flat connection $A^{\prime}$ on $\left(P^{\prime}, \alpha^{\prime}\right)$, and over each ends $\mathbb{R}_{+} \times Y_{j}$ the flat connection $\left.\lim _{t \rightarrow \infty} A^{\prime}\right|_{\{t\} \times Y_{j}}=\alpha_{j}^{\prime}$ corresponds to the representations

$$
\begin{aligned}
\alpha_{1}^{\prime}(g)=e_{+}, & \text {where } g=\left[e_{+}, 1\right] \in G_{1} \\
\alpha_{i}^{\prime}(g)=e_{-}, & \text {where } g=\left[1, e_{-}\right] \in G_{i} \\
\alpha_{j}^{\prime}=1 & \text { if } j \neq 1, i
\end{aligned}
$$

Now the holonomy of $A^{\prime}$ gives a representation $\chi: \pi_{1}\left(X, x_{0}\right) \rightarrow \operatorname{Sp}(1)$ such that the composition $\chi \circ\left(i_{j}\right)_{*}$ is conjugate to the inclusion $G_{j} \hookrightarrow \mathrm{Sp}(1)$ for $j \in\{1, i\}$ and is conjugate to the trivial one otherwise.
(2) If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic, there is a limiting bundle $\left(P^{\prime}, \alpha^{\prime}\right) \prec(P, \alpha)$ with a nontrivial reducible flat connection $A^{\prime}$ and the flat connection $\alpha_{j}^{\prime}$ over each ends $\mathbb{R}_{+} \times Y_{j}$ as above. Now the holonomy representation of $A^{\prime}$ has a reduction to a subgroup $S^{1}$ of $\mathrm{Sp}(1)$ and hence factors through the Hurewicz homomorphism $\pi_{1}\left(X, x_{0}\right) \rightarrow H_{1}(X ; \mathbb{Z})$ to give a character $\chi: H_{1}(X ; \mathbb{Z}) \rightarrow S^{1}$ such that the composition $\chi \circ\left(i_{j}\right)_{*}$ is $\operatorname{Sp}(1)$-conjugate to the inclusion $G_{j} \hookrightarrow S^{1}$ for $j \in\{1, i\}$ and is conjugate to the trivial one otherwise.

This completes the proof of Theorem 4.1.

## 5 Application to a uniformization problem of 4-orbifolds

In this section, we give an application of Theorem 4.1 to a uniformization problem of smooth 4 -orbifolds. Here we recall the notion of orbifolds. For the definitions and basic facts concerning orbifolds see $[30 ; 33]$. A smooth orbifold $(X, \mathcal{F})$ is a pair of a Hausdorff space $X$ and a collection $\mathcal{F}$ of $\left\{\tilde{U}_{\alpha}, G_{\alpha}, \varphi_{\alpha}\right\}$ consisting of an open set $\tilde{U}_{\alpha} \subset \mathbb{R}^{n}$, a finite group $G_{\alpha}$ acting on $\tilde{U}_{\alpha}$ and a homeomorphism $\varphi_{\alpha}: U_{\alpha} \approx \tilde{U}_{\alpha} / G_{\alpha}$ satisfying the property that $\left\{U_{\alpha}\right\}$ is an open covering of $X$ which is closed under
finite intersections and if $U_{\alpha} \subset U_{\beta}$ then there exists an injective homomorphism $h_{\beta \alpha}: G_{\alpha} \hookrightarrow G_{\beta}$ and a smooth embedding $\lambda_{\beta \alpha}: \widetilde{U}_{\alpha} \hookrightarrow \widetilde{U}_{\beta}$ equivariant with respect to $h_{\beta \alpha}$ which induces the inclusion $U_{\alpha} \subset U_{\beta}$.
An orbifold covering map $\pi:(\tilde{X}, \tilde{\mathcal{F}}) \rightarrow(X, \mathcal{F})$ is a continuous map $\pi: \tilde{X} \rightarrow X$ such that each point $x \in X$ has a neighborhood $U$ with a homeomorphism $\varphi: U \approx \tilde{U} / G$ for some $\{\tilde{U}, G, \varphi\} \in \mathcal{F}$ and each component $V_{i} \subset p^{-1}(U)$ admits a homeomorphism $\psi_{i}: V_{i} \approx \tilde{U} / G_{i}$ for some subgroup $G_{i} \subset G$ so that $\left\{\tilde{U}, G_{i}, \psi_{i}\right\} \in \widetilde{\mathcal{F}}$ and the natural projection $\widetilde{U} / G_{i} \rightarrow \widetilde{U} / G$ induces $\pi$ restricted to $U$. If the covering transformation group $\operatorname{Aut}(\pi)$ of $\pi$ is isomorphic to a group $H$ then $\pi$ is called an orbifold $H_{-}$ covering. Suppose a (finite) group $G$ acts on a manifold $M$ properly discontinuously, then $M / G$ has a natural orbifold structure and the natural projection map $\pi: M \rightarrow$ $M / G$ is an orbifold covering map and $M$ is called a (finite) uniformization of $M / G$.

Now Theorem 1.5 is a special case of the following:
Theorem 5.1 Let $X$ be an oriented smooth 4-orbifold with finite isolated singular points $p_{1}, \ldots, p_{s}$ in the interior of $X$ whose neighborhood $U_{i}$ of the singular point $p_{i}$ is homeomorphic to the cone $c Y_{i}$ over a spherical space form $Y_{i}=S^{3} / G_{i}$ for $i \in\{1, \ldots, s\}$ and with boundary a disjoint union of rational homology 3-spheres $\left\{\Sigma_{k}\right\}_{k=1}^{t}$. Suppose that $X$ satisfies the following conditions:
(1) $b_{1}(X)=0$ and $b_{2}^{+}(X)=0$.
(2) $\operatorname{Cok}\left(i_{\Sigma *}: H_{1}(\Sigma ; \mathbb{Z}) \rightarrow H_{1}(X ; \mathbb{Z})\right)=\{0\}$ and $\Sigma=\coprod_{k=1}^{t} \Sigma_{k}$.

Set $m=\max \left\{\left|G_{i}\right| \mid i \in\{1, \ldots, s\}\right\}$. Then there exists a positive constant $N(\Sigma)>0$, depending only on $\Sigma$, such that for any $m>N(\Sigma)$ the following property holds:
Let $U_{1} \approx c Y_{1}$ be the cone over a negative spherical space form $Y_{1}=S^{3} / G_{1}$ satisfying the following conditions:
(1) $\left|G_{1}\right|=m$.
(2) If $G_{1}$ is cyclic, then we assume that

$$
\kappa=\#\left\{e \in H^{2}\left(X-\left\{p_{1}\right\} ; \mathbb{Z}\right) \left\lvert\,(\iota e)^{2}=-\frac{1}{\left|G_{1}\right|}\right., i_{1}^{*} e= \pm e\left(L_{\rho}\right), i_{\Sigma}^{*} e=0\right\} /\{ \pm 1\}
$$

is even, where $\iota$ is the composition

$$
\iota: H^{2}\left(X-\left\{p_{1}\right\} ; \mathbb{Z}\right) \rightarrow H^{2}\left(X-\left\{p_{1}\right\} ; \mathbb{Q}\right) \rightarrow H^{2}(X ; \mathbb{Q}),
$$

$i_{1}: Y_{1} \hookrightarrow X$ is the inclusion and $L_{\rho}=S^{3} \times_{G_{1}} S^{1} \rightarrow Y_{1}$ is the $S^{1}$-bundle associated with the inclusion $\rho: G_{1} \hookrightarrow S^{1} \subset \mathrm{SU}(2)$.
(3) $G_{1}$ is not isomorphic to $\mathbb{Z}_{4}$ or a binary dihedral group.

Then $U_{i} \approx c Y_{i}$ for some positive spherical space form $Y_{i}=S^{3} / G_{i}$ for $i \neq 1$ with $\left|G_{i}\right|=m$ and the following holds:
(1) There exists a smooth orbifold finite Galois covering $\pi: \tilde{X} \rightarrow X$ such that each connected component $V_{j}$ of $\pi^{-1}\left(U_{j}\right)$ is homeomorphic to $V_{j} \approx \mathbb{C}^{2} / H_{j}$, where $H_{j}=\{e\}$ for $j \in\{1, i\}$ and $H_{j}=G_{j}$ otherwise, and the natural map $\mathbb{C}^{2} / H_{j} \rightarrow \mathbb{C}^{2} / G_{j}$ induces $\pi$ restricted to $V_{j}$.
(2) If $\pi_{1}\left(X, x_{0}\right)$ is generated by $\left(i_{\Sigma_{k}}\right) \not{ }_{\#} \pi_{1}\left(\Sigma_{k}, z_{k}\right)$ for $k \in\{1, \ldots, t\}$ with basepoints $x_{0} \in X, z_{k} \in \Sigma_{k}$, where $\left(i_{\Sigma_{k}}\right)_{\#}$ is the homomorphism induced by the inclusion $i_{\Sigma_{k}}: \Sigma_{k} \hookrightarrow X$, there exists $h \in \mathrm{SU}(2)$ and a torsion-free finite-index normal subgroup $N^{\prime}$ of the group $\Gamma^{\prime}$ generated by $G_{1} \cup h G_{i} h^{-1}$ in $\mathrm{SU}(2)$ and a smooth orbifold $\Gamma^{\prime} / N^{\prime}$-covering $\pi: \tilde{X} \rightarrow X$ such that each connected component $V_{j}$ of $\pi^{-1}\left(U_{j}\right)$ is homeomorphic to $V_{j} \approx \mathbb{C}^{2} / H_{j}$, where $H_{j}=\{e\}$ for $j \in\{1, i\}$ and $H_{j}=G_{j}$ otherwise, and the natural map $\mathbb{C}^{2} / H_{j} \rightarrow \mathbb{C}^{2} / G_{j}$ induces $\pi$ restricted to $V_{j}$.
(3) If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic, then $G_{i}=\mathbb{Z}_{m}$ and there exists a smooth orbifold $\mathbb{Z}_{m}$-covering $\pi: \tilde{X} \rightarrow X$ such that each connected component $V_{j}$ of $\pi^{-1}\left(U_{j}\right)$ is homeomorphic to $V_{j} \approx \mathbb{C}^{2} / H_{j}$, where $H_{j}=\{e\}$ for $j \in\{1, i\}$ and $H_{j}=\mathbb{Z}_{m}$ otherwise, and the natural map $\mathbb{C}^{2} / H_{j} \rightarrow \mathbb{C}^{2} / \mathbb{Z}_{m}$ induces $\pi$ restricted to $V_{j}$.

Proof Let $W$ be a 4-manifold obtained by removing the neighborhoods $U_{i} \approx c Y_{i}$ of singular points $p_{i}$ for $i \in\{1, \ldots, s\}$. Then $W$ is a compact smooth 4 -manifold with boundary $Y$ the disjoint union of spherical space forms $Y_{i}=-S^{3} / G_{i}$ for $i \in\{1, \ldots, s\}$ and $t$-components of rational homology 3 -spheres $Y_{s+i}=\Sigma_{i}$ for $i \in\{1, \ldots, t\}$. Since $X$ is negative-definite with respect to the rational intersection pairing $H_{2}(X ; \mathbb{Q}) \times H_{2}(X ; \mathbb{Q}) \rightarrow \mathbb{Q}$ as a rational homology manifold, we see $H_{2}(W ; \mathbb{Q}) \cong H_{2}(X ; \mathbb{Q})$ and therefore $W$ has a negative-definite intersection pairing $H_{2}(W ; \mathbb{Q}) \times H_{2}(W ; \mathbb{Q}) \rightarrow \mathbb{Q}$. By assumption that $i_{\Sigma *}: H_{1}(\Sigma ; \mathbb{Z}) \rightarrow H_{1}(X ; \mathbb{Z})$ is surjective, the homomorphism $i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(W ; \mathbb{Z})$ induced by inclusion $i: Y \hookrightarrow W$ is surjective. Note also that by the assumption

$$
\kappa=\frac{1}{2} \#\left\{e \in H^{2}(W ; \mathbb{Z}) \left\lvert\, e^{2}=-\frac{1}{m}\right., i_{1}^{*} e= \pm e\left(L_{\rho}\right), i_{j}^{*} e=0 \text { if } j \neq 1\right\}
$$

is even, $Y_{1}=-S^{3} / G_{1}$ is a positive spherical space form and $m=\left|G_{1}\right|=\max \left\{\left|G_{i}\right|\right\}>$ $N(\Sigma)$ and $G_{1}$ is not isomorphic to $\mathbb{Z}_{4}$ or a binary dihedral group. Then by Theorem 4.1
we see $\left|G_{i}\right|=\left|G_{1}\right|$ and $Y_{i}=-S^{3} / G_{i}$ is a negative spherical space form for some $i \neq 1$ and there exists a representation $\chi: \pi_{1}\left(W, x_{0}\right) \rightarrow \mathrm{SU}(2)$ such that $\chi \circ\left(i_{j}\right)_{*}$ is the inclusion $\rho: G_{j} \hookrightarrow \mathrm{SU}(2)$ up to $\mathrm{SU}(2)$-conjugation for $j \in\{1, i\}$ and is trivial otherwise, where $\left(i_{j}\right)_{*}=\left(\bar{\delta}_{j}\right)_{*} \circ\left(i_{j}\right)_{\#:} \pi_{1}\left(Y_{j}, y_{j}\right) \rightarrow \pi_{1}\left(W, x_{0}\right)$ is a homomorphism obtained by composing the isomorphism $\left(\delta_{j}\right)_{*}: \pi_{1}\left(X, x_{0}\right) \rightarrow \pi_{1}\left(X, y_{j}\right)$ induced by a path $\delta_{j}$ from $x_{0}$ to $y_{j}$ in $W$ and the homomorphism $\left(i_{j}\right)_{\#: ~} \pi_{1}\left(Y_{j}, y_{j}\right) \rightarrow \pi_{1}\left(W, y_{j}\right)$ induced from the inclusion $i_{j}: Y_{j} \hookrightarrow W$.
(1) Now we have a representation $\chi: \pi_{1}\left(W, x_{0}\right) \rightarrow \mathrm{SU}(2)$. Then we can apply an argument in the proof of Theorem 1.5.10 in [26] due to Namba. Note that the image $\Gamma=\chi\left(\pi_{1}\left(W, x_{0}\right)\right) \subset \mathrm{SU}(2) \subset \mathrm{GL}(2, \mathbb{C})$ is finitely generated and $\Gamma_{j}=\left(\chi \circ i_{j *}\right)\left(G_{j}\right) \subset$ $\mathrm{SU}(2)$ is isomorphic to $G_{j}$ if $j \in\{1, i\}$ and $\Gamma_{j}=\{e\}$ otherwise. By a lemma of A Selberg [31, Lemma 8] - or see an elementary proof in [1] due to R C Alperinthere exists a torsion-free normal subgroup $N$ of $\Gamma$ of finite index. Then we take a quotient $\chi_{N}: \pi_{1}\left(W, x_{0}\right) \rightarrow \Gamma \rightarrow \Gamma / N$. Let $\pi: \widetilde{W} \rightarrow W$ be the $\Gamma / N$-covering space associated with the surjective homomorphism $\chi_{N}: \pi_{1}\left(W, x_{0}\right) \rightarrow \Gamma / N$. Since $\chi \circ\left(i_{j}\right)_{*}$ is conjugate to $\rho: G_{j} \subset \mathrm{SU}(2)$ for $j \in\{1, i\}$, we see $\chi_{N} \circ\left(i_{j}\right)_{*}$ is conjugate to the induced homomorphism $\rho_{N}: G_{j} \subset \Gamma \rightarrow \Gamma / N$. Since $N$ is torsion-free, $N \cap \Gamma_{j}=\{e\}$ and so $\chi_{N} \circ\left(i_{j}\right)_{*}$ is conjugate to an injection $G_{j} \hookrightarrow \Gamma / N$ for $j \in\{1, i\}$. Hence, the group of covering transformations restricted to a single connected component $\widetilde{Y}_{j}$ of the inverse image $\pi^{-1}\left(Y_{j}\right)$ is isomorphic to the image $\bar{\Gamma}_{j}$ of $\Gamma_{j}$ in $\Gamma / N$. For $j \in\{1, i\}$, $\bar{\Gamma}_{j}$ is isomorphic to $G_{j}$, and $\widetilde{Y}_{j} / G_{j} \approx S^{3} / G_{j}$ so that $\widetilde{Y}_{j} \approx S^{3}$, and $\pi^{-1}\left(Y_{j}\right)$ is a disjoint union of $|\Gamma / N| / m$ copies of $S^{3}$. For $j \notin\{1, j\}, \chi \circ\left(i_{j}\right)_{*}=1$ implies $\bar{\Gamma}_{j}=\{e\}$, so that $\pi^{-1}\left(Y_{j}\right)$ is a disjoint union of $|\Gamma / N|$ copies of $Y_{j}=S^{3} / G_{j}$ for $j \in\{1, \ldots, s\} \backslash\{1, i\}$ and $|\Gamma / N|$ copies of $Y_{s+j}=\Sigma_{j}$ for $j \in\{1, \ldots, t\}$. Then the 4 -orbifold $\tilde{X}$ obtained by gluing two $B^{4}$ along $\tilde{Y}_{1}, \widetilde{Y}_{i} \approx S^{3}$ and gluing $\Gamma / N$ copies of $c Y_{j}$ along $Y_{j}=S^{3} / G_{j}$ for each $j \in\{1, \ldots, s\} \backslash\{1, i\}$ and the induced map $\pi: \tilde{X} \rightarrow X$ satisfies the assertion.
(2) Now set $\chi_{j}=\chi \circ\left(i_{j}\right)_{*}$; then, by taking a conjugation if necessary, we may take

$$
\begin{gathered}
\chi_{1}\left(\pi_{1}\left(Y_{1}, y_{1}\right)\right)=\Gamma_{1}, \quad \chi_{i}\left(\pi_{1}\left(Y_{i}, y_{i}\right)\right)=h \Gamma_{i} h^{-1}, \\
\chi_{j}\left(\pi_{1}\left(Y_{j}, y_{j}\right)\right)=\{e\} \quad \text { if } j \notin\{1, i\}
\end{gathered}
$$

for some $h \in \operatorname{SU}(2)$. If $\pi_{1}\left(X, x_{0}\right)$ is generated by $\left(i_{\Sigma_{k}}\right)_{*} \pi_{1}\left(\Sigma_{k}, z_{k}\right)$ for $k \in\{1, \ldots, t\}$, $\pi_{1}\left(W, x_{0}\right)$ is generated by $\left(i_{j}\right)_{*} \pi_{1}\left(Y_{j}, y_{j}\right)$ for $j \in\{1, \ldots, s\}$ and $\left(i_{\Sigma_{k}}\right)_{*} \pi_{1}\left(\Sigma_{k}, z_{k}\right)$ for $k \in\{1, \ldots, t\}$ and hence the representation $\chi$ induces a surjective homomorphism $\chi: \pi_{1}\left(W, x_{0}\right) \rightarrow \Gamma^{\prime}$, where $\Gamma^{\prime}$ is the subgroup of $\operatorname{SU}(2)$ generated by $\Gamma_{1} \cup h \Gamma_{i} h^{-1}$.

Then, by Selberg's lemma again, there exists a torsion-free finite-index normal subgroup $N^{\prime}$ of $\Gamma^{\prime}$, and we take the quotient $\chi_{N^{\prime}}: \pi_{1}\left(W, x_{0}\right) \rightarrow \Gamma^{\prime} \rightarrow \Gamma^{\prime} / N^{\prime}$ to the finite group $\Gamma^{\prime} / N^{\prime}$. Since $N^{\prime}$ is torsion-free, $N^{\prime} \cap \Gamma_{1}=\{e\}$ and $N^{\prime} \cap h \Gamma_{i} h^{-1}=\{e\}$, so that the maps $\Gamma^{\prime} \rightarrow \Gamma^{\prime} / N^{\prime}$ restricted to $\Gamma_{1}$ and $h \Gamma_{i} h^{-1}$ are injective. Let $\pi: \widetilde{W} \rightarrow W$ be the $\Gamma^{\prime} / N^{\prime}-$ covering space associated with the surjective homomorphism $\chi_{N}^{\prime}: \pi_{1}\left(W, x_{0}\right) \rightarrow \Gamma^{\prime} / N^{\prime}$. Since $\chi \circ\left(i_{j}\right)_{*} \cong \rho, \rho: G_{j} \subset \mathrm{SU}(2)$ for $j \in\{1, i\}$, the group of covering transformations restricted to a single connected component $\tilde{Y}_{j}$ of the inverse image $\pi^{-1}\left(Y_{j}\right)$ is isomorphic to the image $\bar{\Gamma}_{j}$ of $\Gamma_{j}$ in $\Gamma^{\prime} / N^{\prime}$. For $j \in\{1, i\}, \bar{\Gamma}_{j}$ is isomorphic to $G_{j}$, and $\tilde{Y}_{j} / G_{j} \approx S^{3} / G_{j}$, so that $\tilde{Y}_{j} \approx S^{3}$, and $\pi^{-1}\left(Y_{j}\right)$ is a disjoint union of $\left|\Gamma^{\prime} / N^{\prime}\right| / m$ copies of $S^{3}$. For $j \notin\{1, j\}, \chi_{N^{\prime}} \circ\left(i_{j}\right)_{*}=1$ implies $\bar{\Gamma}_{j}^{\prime}=\{e\}$, so that $\pi^{-1}\left(Y_{j}\right)$ is a disjoint union of $\left|\Gamma^{\prime} / N^{\prime}\right|$ copies of $Y_{j}=S^{3} / G_{j}$ for $j \in\{1, \ldots, s\} \backslash\{1, i\}$ and $\left|\Gamma^{\prime} / N^{\prime}\right|$ copies of $Y_{s+j}=\Sigma_{j}$ for $j \in\{1, \ldots, t\}$. Then the 4 -orbifold $\tilde{X}$ obtained by gluing $\left|\Gamma^{\prime} / N^{\prime}\right| / m$ copies of $B^{4}$ along $\tilde{Y}_{j} \approx S^{3}$ for $j \in\{1, i\}$ and gluing $\left|\Gamma^{\prime} / N^{\prime}\right|$ copies of $c Y_{j}$ along $Y_{j}=S^{3} / G_{j}$ for each $j \in\{1, \ldots, s\}-\{1, i\}$ and the induced map $\pi: \tilde{X} \rightarrow X$ satisfies the assertion.
(3) If all $G_{j}$ with $\left|G_{j}\right|=m$ are cyclic, then by Theorem 4.1 we see $Y_{i}=L(m,-1)$ for some $i \neq 1$ and there exists a character $\chi: H_{1}(W ; \mathbb{Z}) \rightarrow U(1)$ such that $\chi \circ i_{j *}$ is the inclusion $\rho$ : $\mathbb{Z}_{m} \hookrightarrow U(1)$ up to complex conjugation for $j \in\{1, i\}$ and is trivial otherwise. Since $i_{*}: H_{1}(Y ; \mathbb{Z}) \rightarrow H_{1}(W ; \mathbb{Z})$ is surjective, we see the character $\chi$ induces the surjective homomorphism $\chi: H_{1}(W ; \mathbb{Z}) \rightarrow \mathbb{Z}_{m}$. Let $\pi: \widetilde{W} \rightarrow W$ be the $\mathbb{Z}_{m}$-covering space associated with the surjective homomorphism $\pi_{1}(W) \rightarrow H_{1}(W ; \mathbb{Z}) \rightarrow \mathbb{Z}_{m}$ obtained by composing $\chi$ with the Hurewicz homomorphism. Since $\chi \circ i_{j *}=\rho^{ \pm 1}$ and $\rho$ : $\mathbb{Z}_{m} \subset U(1)$ for $j \in\{1, i\}$, the group $G_{j}$ of covering transformations $g \in \mathbb{Z}_{m}$ is the cyclic group $\mathbb{Z}_{m}$ itself and acting on the single connected component $\tilde{Y}_{j}$ of the inverse image $\pi^{-1}\left(Y_{j}\right)$ with $\widetilde{Y}_{j} / \mathbb{Z}_{m} \approx L(m, \pm 1)$, so that $\tilde{Y}=S^{3}$. On the other hand, $\chi \circ i_{j *}=1$ for $j \notin\{1, j\}$ implies that $\pi^{-1}\left(Y_{j}\right)$ is a disjoint union of $m$ copies of $Y_{j}=L\left(a_{j}, b_{j}\right)$ for $j \in\{1, \ldots, s\} \backslash\{1, i\}$ and $m$ copies of $Y_{s+j}=\Sigma_{j}$ for $j \in\{1, \ldots, t\}$. Then the 4 -orbifold $\tilde{X}$ obtained by gluing two $B^{4}$ along $\tilde{Y}_{1}, \widetilde{Y}_{i} \approx S^{3}$ and gluing $m$ copies of $c L\left(a_{j}, b_{j}\right)$ along $Y_{j}=L\left(a_{j}, b_{j}\right)$ for each $j \in\{1, \ldots, s\} \backslash\{1, i\}$ and the induced map $\pi: \widetilde{X} \rightarrow X$ satisfies the assertion.
