

## A NOTE ON ABELIAN GALOIS ALGEBRA OVER A COMMUTATIVE RING

TERUO KANZAKI

(Received September 6, 1965)

Let  $\Lambda$  be a faithful algebra over a commutative ring  $R$  with unit element 1, and  $G$  a finite group of  $R$ -algebra automorphisms of  $\Lambda$ . In the following we shall identify  $R \cdot 1$  with  $R$ . We shall call  $\Lambda$  a (central, abelian) Galois algebra over  $R$  with group  $G$ , if  $\Lambda$  is a Galois extension of (the center)  $R$  relative to (abelian) group  $G$  in the sense of [1], [7] and [8]. In [3], Chase, Harrison and Rosenberg proved the normal basis theorem for a commutative Galois algebra over a semi-local ring, and in [5], De Meyer proved it for a central abelian Galois algebra  $\Lambda$  over its center with group of inner automorphisms of  $\Lambda$ . In this note, in §1, we shall prove the normal basis theorem for any abelian Galois algebra over a semi-local ring. Furthermore, we show that if the normal basis theorem holds for an  $R$ -algebra  $\Lambda$  with a finite abelian group  $G$  of  $R$ -algebra automorphisms of  $\Lambda$ , and if  $\Lambda$  is a strongly separable algebra (see [9]) then  $\Lambda$  is a Galois algebra over  $R$  with  $G$ . In §2 and §3, we shall show some properties an abelian Galois algebra over an indecomposable commutative ring. Throughout this note, we assume that every ring has a unit element.

**1. Normal basis.** Let  $\Lambda$  be an algebra over a commutative ring, and  $G$  a finite abelian group of  $R$ -algebra automorphisms of  $\Lambda$ .

**Theorem 1.** *Let  $R$  be a local ring, and  $\Lambda$  an abelian Galois algebra over  $R$  with abelian group  $G$ . Then  $\Lambda$  is isomorphic to the group ring  $RG$  of group  $G$  over ring  $R$  as  $RG$ -module.*

**Proof.** Since  $R$  is local and  $G$  is abelian, by [10],  $\Lambda$  is a Galois extension of the center  $C$  with the subgroup  $H$  and the center  $C$  is a Galois extension of  $R$  with group  $G/H$ , where  $H = \{\sigma \in G : \sigma|_C = \text{identity}\}$ . Therefore,  $\Lambda \otimes_R C$  is a Galois extension of the center  $C \otimes_R C$  with group  $H$  and  $C \otimes_R C$  is a Galois extension of  $R \otimes_R C = C$  with group  $G/H$ . Let  $\{\sigma_1 = 1, \sigma_2, \dots, \sigma_r\}$  be a representative system of the residue class group

$G/H$ . By [3],  $C \otimes_R C = \sum_{i=1}^r \oplus C e_{\sigma_i} = \sum_{i=1}^r \oplus C \sigma_i(e_1)$ , where  $e_1, e_{\sigma_2}, \dots, e_{\sigma_r}$  are orthogonal idempotent elements in  $C \otimes_R C$  and  $\sum_{i=1}^r e_{\sigma_i} = 1$ , and hence  $\Lambda \otimes_R C = \sum_{i=1}^r \oplus (\Lambda \otimes_R C) \sigma_i(e_1) = \sum_{i=1}^r \oplus \sigma_i(\Lambda \otimes_R C) e_1$ . On the other hand,  $(\Lambda \otimes_R C) e_1$  is a central Galois extension of  $C e_1 = (C \otimes_R C) e_1$  with group  $H$ . Since  $C$  is semi-local, by Lemma 1 in [10],  $H$  is a group of inner automorphisms of  $(\Lambda \otimes_R C) e_1$ . By [5], there is an element  $\vartheta$  in  $(\Lambda \otimes_R C) e_1$  such that  $(\Lambda \otimes_R C) e_1 = \sum_{\tau \in H} \oplus C \tau(\vartheta)$ . Therefore, we have

$$\Lambda \otimes_R C = \sum_{i=1}^r \oplus \sigma_i((\Lambda \otimes_R C) e_1) = \sum_{i=1, \tau \in H} \oplus C \sigma_i \tau(\vartheta) = \sum_{\tau \in G} \oplus C \sigma(\vartheta).$$

Hence  $\Lambda \otimes_R C$  is isomorphic to the group ring  $CG$  of group  $G$  over ring  $C$  as  $CG$ -module. Since  $C$  is a finite rank  $R$ -free module,  $CG$  is a finitely generated  $RG$ -projective module and  $\Lambda \otimes_R C$  is a finitely generated  $RG$ -projective module. Since  $R$  is a direct summand of  $C$  as  $R$ -module,  $\Lambda$  is a finitely generated projective  $RG$ -module. For the remainder of the proof, we proceed similarly to the proof of Theorem 4.2 in [3]. For the maximal ideal  $\mathfrak{m}$  of  $R$ , we have  $\Lambda \otimes_R C / \mathfrak{m}C \cong RG \otimes_R R / \mathfrak{m}C$ . Using the Krull-Schmidt Theorem, we obtain  $\Lambda / \mathfrak{m}\Lambda \cong R / \mathfrak{m}G$  as  $R / \mathfrak{m}G$ -module. Since  $\mathfrak{m}RG$  is a radical ideal of the group ring  $RG$ , and  $\Lambda$  is a  $RG$ -projective module, by Lemma 3.14 in [11]  $\Lambda$  and  $RG$  are isomorphic  $RG$ -modules.

**Corollary 1.** *Let  $\Lambda$  be an abelian Galois algebra over  $R$  with abelian group  $G$ . Then  $\Lambda$  is a finitely generated rank 1  $RG$ -projective module, and therefore  $\Lambda$  is a rank  $|G|$   $R$ -projective module ( $|G|$  denotes the order of  $G$ ).*

*Proof.* Since  $RG$  is a commutative ring, for any prime ideal  $P$  of  $RG$

$$\Lambda \otimes_{RG} (RG)_P = (\Lambda \otimes_R R_p) \otimes_{R_p G} (RG)_P$$

where  $p = R \cap P$ . By Theorem 1,  $\Lambda \otimes_R R_p \cong R_p G$  as  $R_p G$ -module, hence  $\Lambda \otimes_{RG} (RG)_P \cong (RG)_P$  as  $(RG)_P$ -module. Therefore, by p. 138, Theorem 1 in [2],  $\Lambda$  is an  $RG$ -projective module with rank 1.

**Corollary 2.** *Let  $R$  be a semi-local ring,  $\Lambda$  an abelian Galois algebra over  $R$  with abelian group  $G$ . Then  $\Lambda$  is isomorphic to  $RG$  as  $RG$ -module.*

*Proof.* By Corollary 1,  $\Lambda$  is a finitely generated rank 1  $RG$ -projective module. If  $R$  is a semi-local ring, then  $RG$  is also semi-local, therefore by p. 143, Proposition 5 in [2],  $\Lambda$  is  $RG$ -free module with rank 1.

**Theorem 2.** *Let  $\Lambda$  be an algebra over a commutative ring  $R$  with*

unit element, and  $G$  a finite abelian group of  $R$ -algebra automorphisms of  $\Lambda$ . If  $\Lambda$  is isomorphic to the group ring  $RG$  as  $RC$ -module, and if  $\Lambda$  is a strongly separable algebra over  $R$  (see [9]), then  $\Lambda$  is a Galois algebra over  $R$  with group  $G$ .

Before proving the Theorem, we prove the following lemma.

**Lemma 1.** *Let  $\Lambda$  be an algebra over  $R$ , and  $G$  a finite group of  $R$ -algebra automorphisms of  $\Lambda$ . If  $\Lambda$  is strongly separable over  $R$  and  $Tr(\Lambda) \ni 1$ , where  $Tr(x) = \sum_{\sigma \in G} \sigma(x)$  for  $x \in \Lambda$ , then a crossed product  $\Delta(\Lambda, G)$  of  $\Lambda$  and  $G$  with trivial factor set is separable over  $R$ .*

Prof. Let  $\Delta(\Lambda, G) = \sum_{\sigma \in G} \oplus \Lambda u_{\sigma}$ ,  $u_{\sigma} u_{\tau} = u_{\sigma\tau}$ , and  $u_{\sigma} \lambda = \sigma(\lambda) u_{\sigma}$  for  $\lambda \in \Lambda$ . We set  $A =$  right annihilator of  $\ker \varphi$  in  $\Delta(\Lambda, G)^e = \Delta(\Lambda, G) \otimes_R (\Delta(\Lambda, G))^0$ , where  $\varphi: \Delta(\Lambda, G) \otimes_R (\Delta(\Lambda, G))^0 \rightarrow \Delta(\Lambda, G)$  is defined by  $\varphi(x \otimes y) = xy$ , and set  $A =$  right annihilator of  $\ker \varphi$  in  $\Lambda^e = \Lambda \otimes_R \Lambda^0$ , where  $\varphi: \Lambda \otimes_R \Lambda^0 \rightarrow \Lambda$  is defined by  $\varphi(x \otimes y) = xy$ . From the proof of Theorem 4 in [7], it follows that  $A$  contains the elements  $\sum_{\gamma \in G} \gamma \times \gamma(a) u_{\gamma} \otimes u_{\gamma^{-1}}^0$  in  $\Delta(\Lambda, G)^e$  for every  $a$  in  $A$ . Therefore,  $\varphi(\sum_{\gamma \in G} \gamma \times \gamma(a) u_{\gamma} \otimes u_{\gamma^{-1}}^0) = Tr(\varphi(a))$  is contained in  $\varphi(A)$ . Since  $\Lambda$  is strongly separable over  $R$ ,  $\Lambda$  is separable over  $R$  and  $\Lambda = C \oplus [\Lambda, \Lambda]$ . Thus  $\varphi(A) \supset Tr(\varphi(A)) = Tr(C)$ . Since  $Tr(\Lambda) \ni 1$ , there exists  $a = c + b$  in  $\Lambda = C \oplus [\Lambda, \Lambda]$  such that  $Tr(a) = Tr(c) + Tr(b) = 1$ ,  $c \in C$ ,  $b \in [\Lambda, \Lambda]$ , therefore  $Tr(C) \ni Tr(c) = 1$ . Accordingly,  $\varphi(A) \ni 1$ ,  $\Delta(\Lambda, G)$  is separable over  $R$ .

We have easily the following lemma.

**Lemma 2.** *Let  $\Lambda$  be a faithful algebra over  $R$ ,  $G$  a finite abelian group of  $R$ -algebra automorphisms of  $\Lambda$ , and let  $\Lambda^G = R$ . Then an element  $\sum_{\sigma \in G} \lambda_{\sigma} u_{\sigma}$  of the crossed product  $\Delta(\Lambda, G)$  is contained in its center if and only if  $\lambda_{\sigma}$  is in  $R$  for ever  $\sigma \in G$  and satisfies  $\lambda_{\sigma} \sigma(\lambda) = \lambda \lambda_{\sigma}$  for every  $\lambda \in \Lambda$  and  $\sigma \in G$ .*

Proof of Theorem 2. We suppose  $\Lambda = \sum_{\sigma \in G} \oplus R \sigma(\vartheta)$  for some element  $\vartheta$  in  $\Lambda$ . We have easily  $\Lambda^G = R Tr(\vartheta) = Tr(\Lambda)$ . Since  $\Lambda^G$  is a ring and contains  $R$ ,  $Tr(\vartheta)$  is contained in  $R$ , therefore  $\Lambda^G = Tr(\Lambda) = R$ . By Lemma 1, the crossed product  $\Delta(\Lambda, G)$  is separable over  $R$ , and by Lemma 2, the center of  $\Delta(\Lambda, G)$  is  $R$ . Because, if  $\sum_{\sigma \in G} \lambda_{\sigma} u_{\sigma}$  is any element of the center of  $\Delta(\Lambda, G)$ , then  $\lambda_{\sigma} \in R$  and  $\lambda_{\sigma} \sigma(\vartheta) = \lambda_{\sigma} \vartheta$  for every  $\sigma \in G$ , hence  $\lambda_{\sigma} = 0$  for  $\sigma \neq 1$ . Therefore,  $\Delta(\Lambda, G)$  is a central separable algebra over

$R$ . Now, we consider the natural homomorphism  $\delta: \Delta(\Lambda, G) \rightarrow \text{Hom}_R(\Lambda, \Lambda)$ . By [1],  $\text{Hom}_R(\Lambda, \Lambda)$  and  $\text{Im } \delta$  are central separable algebras over  $R$ . Since the commutor ring  $V_{\text{Hom}_R(\Lambda, \Lambda)}(\text{Im } \delta)$  of  $\text{Im } \delta$  in  $\text{Hom}_R(\Lambda, \Lambda)$  is  $R$ , by Lemma 2.3 in [4],  $\delta$  is an isomorphism. Therefore,  $\Lambda$  is a Galois extension of  $R$  with group  $G$ .

**REMARK.** By Proposition 8 in [10], an abelian Galois algebra  $\Lambda$  over any commutative ring  $R$  with abelian group  $G$  is strongly separable over  $R$ . Therefore if  $R$  is a semi-local ring, then  $\Lambda$  is a Galois algebra over  $R$  with abelian group  $G$  if and only if  $\Lambda$  is a strongly separable algebra and a Galois algebra over  $R$  with abelian group  $G$  in the sense of Hasse [6] or Wolf [13].

**2. Splitting ring.** In this section, we shall show that an abelian Galois algebra over a local ring has a splitting ring.

**Theorem 3.** *Let  $\Lambda$  be an abelian Galois algebra over a commutative ring  $R$  with abelian group  $G$ . If  $R$  is indecomposable, then there exist a maximal commutative subalgebra  $S$  of  $\Lambda$  and a subgroup  $G_1$  of  $G$  such that  $\Lambda^{G_1} = S$ . Therefore,  $S$  is a commutative Galois extension of  $R$  with group  $G/G_1$  and  $\Lambda$  is a finitely generated projective  $S$ -module. Thus, if  $C$  is the center of  $\Lambda$  then central separable algebra  $\Lambda$  over  $C$  is split by  $S$  in the sense of [1]. In particular, if  $R$  is a local ring, then  $\Lambda \otimes_R R$  is isomorphic to the full matrix ring of degree  $|G_1|$  over the commutative ring  $C \otimes_R S = \sum_{\bar{\sigma} \in G/H} \oplus S e_{\bar{\sigma}}$  where  $H = \{\sigma \in G : \sigma|_C = \text{identity}\}$ ,  $\{e_{\bar{\sigma}} : \bar{\sigma} \in G/H\}$  are orthogonal idempotent elements and  $\sum_{\bar{\sigma} \in G/H} e_{\bar{\sigma}} = 1$ .*

**Proof.** For the first part, we prove by the induction on the order  $|G|$ . If  $|G|$  is prime, then by [5],  $\Lambda$  is commutative, i.e.  $\Lambda = S$ . We suppose  $\Lambda$  is non-commutative. Since  $R$  is indecomposable, by [10],  $\Lambda$  is a Galois extension of the center  $C$  with group  $H$ , and  $\Lambda = \sum_{\sigma \in H} \oplus J_{\sigma}$ ,  $J_{\sigma} = \{a \in \Lambda : \sigma(x)a = ax \text{ for all } x \in \Lambda\}$ . By [5], we may assume that  $H$  is not cyclic. For an element  $\sigma$  in  $H$ , we denote the  $\sigma$ -fixed subring of  $\Lambda$  by  $\Lambda^{(\sigma)}$ , then the commutor ring  $V_{\Lambda}(\Lambda^{(\sigma)}) = \sum_i \oplus J_{\sigma^i}$  is the center of  $\Lambda$  (cf. [10]). Since  $\Lambda^{(\sigma)}$  is a Galois extension of  $R$  with group  $G/(\sigma)$ , using the inductive assumption on order  $|G/(\sigma)|$ , there exist a maximal commutative subalgebra  $S$  of  $\Lambda$  and a subgroup  $\bar{G}_1 = G_1/(\sigma)$  of  $G/(\sigma)$  such that  $(\Lambda^{(\sigma)})^{G_1} = \Lambda^{G_1} = S$ . But  $\Lambda^{(\sigma)} \supset S \supset V_{\Lambda}(\Lambda^{(\sigma)})$ , hence  $V_{\Lambda}(S) \subset (\Lambda^{(\sigma)})$ , therefore  $V_{\Lambda}(S) = S$ . Accordingly,  $S$  is a maximal commutative subalgebra of  $\Lambda$ . Since  $S$  is a Galois extension of  $R$  with group  $G/G_1$ ,  $S$  is separable over

$R$ , therefore  $\Lambda$  is a finitely generated projective  $S$ -module (see [7]). By Proposition 2.4 in [4], central separable algebra  $\Lambda$  over  $C$  is split by  $S$ . Thus we have the first part. For the last part, we assume  $R$  is local. Then  $S$  is a semi-local ring and by §5, Proposition 5 in [2],  $\Lambda$  is a  $S$ -free module with rank  $|G_1|=m$ . By Proposition 2.4 in [4],  $\Lambda \otimes_C S = \text{Hom}_S(\Lambda, \Lambda) = (S)_m$ . On the other hand, by [3],  $C \otimes_R C = \sum_{\bar{\sigma} \in G/H} \oplus C\ell_{\bar{\sigma}}$ , and therefore

$$\begin{aligned} \Lambda \otimes_R S &= (\Lambda \otimes_C S) \otimes_C (C \otimes_R C) = (S)_m \otimes_C (C \otimes_R C) = (S)_m \otimes_S (S \otimes_R C) \\ &= \left( \sum_{\bar{\sigma} \in G/H} \oplus S\ell_{\bar{\sigma}} \right)_m. \end{aligned}$$

### 3. Central Galois extension

**Lemma 3.** *Let  $C$  be any commutative ring, and  $G$  a finite group such that the order  $|G|$  is unit in  $C$ . Then for any  $CG$ -module  $M$ ,  $M^G = \{x \in M : \sigma x = x \text{ for all } \sigma \in G\}$  is a direct summand of  $M$  as  $C$ -module.*

*Proof.*  $\text{Tr}'(x) = \frac{1}{|G|} \sum_{\sigma \in G} \sigma(x)$  for  $x \in M$ . Then  $\text{Tr}' : M \rightarrow M^G$  is a  $C$ -epimorphism, and  $\text{Tr}'|_{M^G} = \text{identity}$ , therefore,  $M^G$  is a direct summand of  $M$  as  $C$ -module.

**Theorem 4.** *Let  $\Lambda$  be a central abelian Galois extension of the center  $C$  with abelian group  $G$ , and  $C$  an indecomposable ring. Then*

- 1) *for every subgroup  $H$  of  $G$ , there exists a subgroup  $H'$  of  $G$  such that  $\Lambda^H = \sum_{\sigma \in H'} \oplus J_{\sigma}$ ,*
- 2) *if  $\Lambda^H = \sum_{\sigma \in H'} \oplus J_{\sigma}$  then  $\Lambda^H = V_{\Lambda}(\Lambda^{H'})$  and  $\Lambda^{H'} = V_{\Lambda}(\Lambda^H)$ .*

*Proof.* By [10],  $\Lambda = \sum_{\sigma \in G} \oplus J_{\sigma}$  and  $|G|$  is unit in  $C$ . Since  $\sigma(J_{\tau}) = J_{\sigma\tau\sigma^{-1}} = J_{\sigma}$  (see [10],  $J_{\tau}$  is  $CG$ -module. For any subgroup  $H$  of  $G$ , by Lemma 3,  $J_{\tau}^H$  is a finitely generated projective  $C$ -module. Since  $C$  is indecomposable, for every maximal ideal  $p$  of  $C$ , rank of  $J_{\tau}^H \otimes_C C_p$  over  $C_p$  is constant (see p. 138, Theorem 1 in [2]), hence  $J_{\tau}^H \otimes_C C_p \neq 0$  for every maximal ideal  $p$  of  $C$  if  $J_{\tau}^H \neq 0$ . Since  $J_{\tau}$  is a rank 1 projective  $C$ -module (see [12]), we have  $J_{\tau}^H \otimes_C C_p = J_{\tau} \otimes_C C_p$  for every maximal ideal  $p$  of  $C$  if  $J_{\tau}^H \neq 0$ . Therefore, we have either  $J_{\tau}^H = 0$  or  $J_{\tau}^H = J_{\tau}$  for each  $\tau \in G$ . Accordingly,  $\Lambda^H = \sum_{\sigma \in G} \oplus J_{\sigma}^H = \sum_{\tau \in H'} \oplus J_{\tau}$ , where  $H' = \{\tau \in G : J_{\tau}^H = J_{\tau}\}$ . Since  $\Lambda^H$  is a subring, by [10],  $H'$  is a subgroup of  $G$ . Since  $\Lambda^{H'}$  is separable over  $C$ ,  $T_{\Lambda}(\Lambda^{H'}) = \sum_{\tau \in H'} \oplus J_{\tau} = \Lambda^H$  is separable over  $C$ , and  $V_{\Lambda}(V_{\Lambda}(\Lambda^{H'})) = \Lambda^{H'}$  (see [7]). Therefore,  $V_{\Lambda}(\Lambda^H) = \Lambda^{H'}$  and  $V_{\Lambda}(\Lambda^{H'}) = \Lambda^H$ .
