# A GENERALIZATION OF A THEOREM OF MILNOR 

Dedicated to Professor Seiya Sasao on his 60th birthday

## Fumihiro USHITAKI

(Received October 29, 1992)

## 1. Introduction

We work in the smooth category with free actions by groups in the present paper. Let us recall Milnor's theorem:

Theorem 1.1 ([6; Corollary 12.13]). Any h-cobordism $W$ between lens spaces $L$ and $L^{\prime}$ must be diffeomorphic to $L \times[0,1]$ if the dimension of $L$ is greater than or equal to 5.

Let $Z_{m}$ be the cyclic group of order $m$. Then we see that Theorem 1.1 is put in another way as follows:

Theorem 1.2. Let $S(V)$ and $S\left(V^{\prime}\right)$ be free linear $Z_{m}$-spheres of dimension $2 n-1 \geqq 5$. Then any $Z_{m}$-h-cobordism $W$ between $S(V)$ and $S\left(V^{\prime}\right)$ must be $Z_{m^{-}}$-diffeomorphic to $S(V) \times I$, where $I=[0,1]$.

Let $R$ be a ring with unit, $G$ a finite group. Put $G L(R)=\underline{\varliminf} G L_{n}(R)$ and $E(R)=[G L(R), G L(R)]$ the commutator subgroup of $G L(R)$. Then $K_{1}(R)$ denotes the quotient group $G L(R) / E(R)$. Let $Z$ be the ring of integers and $Q$ the ring of rational munbers. Let $Z[G]$ and $Q[G]$ denote the group rings of $G$ over $\boldsymbol{Z}$ and $\boldsymbol{Q}$. The Whitehead group of $\boldsymbol{G}$ is the quotient group

$$
W h(G)=K_{1}(Z[G]) /< \pm g: g \in G>.
$$

The natural inclusion map $i: G L(Z[G]) \rightarrow G L(Q[G])$ gives rise to a group homomorphism $i_{*}: K_{1}(Z[G]) \rightarrow K_{1}(Q[G])$. Then $S K_{1}(Z[G])$ is defined by setting

$$
S K_{1}(Z[G])=\operatorname{ker}\left[i_{*}: K_{1}(Z[G]) \rightarrow K_{1}(Q[G])\right] .
$$

In [15], C.T.C. Wall showed that $S K_{1}(Z[G])$ is isomorphic to the torsion
subgroup of $W h(G)$. We will apply the following algebraic result to extend Theorem 1.2.

Theorem A. Let $G$ be a finite group which can act linearly and freely on spheres. Then $S K_{1}(Z[G])=0$ if and only if $G$ is isomorphic to one of the following groups.
(1) A cyclic group.
(2) A group of type I in Appendix(a metacyclic group with certain condition).
(3) $A$ quaternionic group $\mathbf{Q}(8 t)$ with generators $B, R$ and relations $B^{4 t}=1, B^{2 t}=R^{2}=(B R)^{2}$, where $t \geqq 1$.
(4) $A$ group $\mathbf{Q}\left(8 t, m_{1}, m_{2}\right)$ generated by $A, B, R$ with relations $A^{m_{1} m_{2}}=B^{4 t}=1, B A B^{-1}=A^{-1}, R^{2}=B^{2 t}, R A R^{-1}=A^{l}, R B R^{-1}=$ $B^{-1}$, where $m_{1}, m_{2} \geqq 1, \quad m_{1} m_{2}>1, \quad\left(m_{1}, m_{2}\right)=1, \quad\left(2 t, m_{1} m_{2}\right)=1$, $l \equiv-1\left(m_{1}\right), l \equiv 1\left(m_{2}\right)$.
(5) The binary tetrahedral group $\mathbf{T}^{*}$.
(6) $A$ generalized binary octahedral group $\mathrm{O}^{*}(48 t)$ generated by $B, P, Q, R$ with relations $B^{3 t}=1, P^{2}=Q^{2}=(P Q)^{2}=R^{2}, B P B^{-1}=$ $Q, B Q B^{-1}=P Q, R P R^{-1}=Q P, R Q R^{-1}=Q^{-1}, R B R^{-1}=B^{-1}$, where $t$ is odd.
(7) The binary icosahedral group $\mathrm{I}^{*}=S L(2,5)$.
(8) The group generated by $S L(2,5)$ and an element $S$, where $S^{2}=-1 \in S L(2,5), S L S^{-1}=\left(\begin{array}{cc}0 & -1 \\ 2 & 0\end{array}\right) L\left(\begin{array}{cc}0 & -1 \\ 2 & 0\end{array}\right)^{-1}$ for $L \in S L(2,5)$.

We obtain the following applications of Theorem A as generalizations of Theorem 1.2.

Example B. Let $G$ be a finite group in Theorem A. Let $X$ be a free $G$-homotopy sphere of dimension $2 n-1 \geqq 5$, and let $S(V)$ and $S\left(V^{\prime}\right)$ be free linear $G$-spheres of dimension $2 n-1 \geqq 5$. Then,
(1) Any $G$ - $h$-cobordism $W$ between $X$ and itself must be $G$-diffeomorphic to $X \times I$.
(2) Any $G$ - $h$-cobordism $W$ between $S(V)$ and $S\left(V^{\prime}\right)$ must be $G$-diffeomorphic to $S(V) \times I$.

Example C. Let $G$ be a finite group. Let $X$ be a free $G$-homotopy sphere of dimension $4 n+1 \geqq 5$, and let $S(V)$ and $S\left(V^{\prime}\right)$ be free linear $G$-spheres of dimension $4 n+1 \geqq 5$. Then,
(1) Any $G$ - $h$-cobordism $W$ between $X$ and itself must be $G$-diffeomorphic to $X \times I$.
(2) Any $G$-h-cobordism $W$ between $S(V)$ and $S\left(V^{\prime}\right)$ must be $G$-diffeomorphic to $S(V) \times I$.

When $G$ is a compact Lie group of positive dimension, a generalization of Theorem 1.2 is:

Theorem D. Let $G$ be a compact Lie group of positive dimension which can act freely on spheres. Let $X^{m}$ and $X^{\prime m}$ be free G-homotopy spheres of dimension $m$, and let $\left(W ; X, X^{\prime}\right)$ be a $G$-h-cobordism of a free $G$-action.
(1) If $G=S^{1}$ and $m=2 n-1 \geqq 7$, then $W$ must be $S^{1}$-diffeomorphic to $X \times I$.
(2) If $G=N S^{1}$ and $m=4 n-1 \geqq 7$, then $W$ must be $N S^{1}$-diffeomorphic to $X \times I$ where $N S^{1}$ is the normalizer of $S^{1}$ in $S^{3}$.
(3) If $G=S^{3}$ and $m=4 n-1 \geqq 11$, then $W$ must be $S^{3}$-diffeomorphic to $X \times I$.

This paper is organized as follws: Section 2 presents the proof of Theorem A. In section 3 we prove Examples B and C, and state some results on $G$ - $h$-cobordisms between $G$-homotopy spheres. We prove Theorem D in section 4. Appendix is devoted to quoting the table of the finite solvable groups which can act linearly and freely on odd dimensional spheres from [16].

## 2. Proof of Theorem $A$

First, let $G$ be a finite solvable group which can act linearly and freely on spheres. As in [16; Theorem 6.1.11], there are 4 types for such kinds of groups. For the convenience of the readers, the table of these groups are cited in Appendix. We now recall the structure of $S K_{1}(Z[G])$ of these groups $G$. We must prepare the following notations.

Let $G_{1}, G_{2}, G_{3}$ and $G_{4}$ denote the groups of type I, II, III and IV respectively mentioned in the table in Appendix. Let ( $a_{1}, a_{2}, \cdots, a_{\lambda}$ ) denote the greatest common divisor of integers $\left\{a_{1}, a_{2}, \cdots, a_{\lambda}\right\}$, and let $m, n, r, l, k, u, v$ and $d$ be the integers appeared in the definition of $G_{1}, G_{2}$, $G_{3}$ and $G_{4}$. For positive integers $\alpha, \beta, \gamma$ and $\delta$, put

$$
\begin{aligned}
& M_{\beta}=\left(r^{\beta}-1, m\right) \\
& D(\alpha)=\{x \in N \mid x \text { is a divisor of } \alpha\} \\
& D(\alpha, \beta)=\{x \in D(\alpha) \mid x \text { can be divided by } \beta\}
\end{aligned}
$$

$$
\begin{aligned}
& D(\alpha)_{\gamma}^{\delta}=\{x \in D(\alpha) \mid x \gamma \equiv 0(\delta)\} \\
& D(\alpha, \beta)_{\gamma}^{\delta}=\{x \in D(\alpha, \beta) \mid x \gamma \equiv 0(\delta)\}
\end{aligned}
$$

If $d$ is an even integer, we put $d^{\prime}=d / 2$, and put

$$
\begin{aligned}
t(2)= & \#\left\{(\alpha, \beta) \mid \beta \in D(v)_{k-1}^{v}, \alpha \in D\left(M_{2^{u} \beta}\right),\right. \\
& \left(\alpha+a M_{2^{u} \beta}\right)\left(l-1, r^{n / 4}-1\right) \equiv 0(m) \\
& \text { for some integer } \left.a \text { with } 0 \leqq a<m / M_{2^{u} \beta}\right\} \\
& -\# \bigcup_{\substack{0 \leq b<d \\
\lambda=0,1}} D(m)_{\left(l-1, r^{n / 4}-1, l^{2} r^{b}+1\right),}^{m} \\
t^{\prime}(2)= & \#(\alpha, \beta) \mid \beta \in D(v)_{k-1}^{v}, \alpha \in D\left(M_{2^{u} \beta}\right), \\
& \left(\alpha+a M_{2^{u} \beta}\right)\left(l-1, r^{n / 4}-1\right) \equiv 0(m) \text { or } \\
& \left(\alpha+a M_{2^{u} \beta}\right)\left(l r^{d^{\prime}}-1, r^{n / 4}-1\right) \equiv 0(m) \\
& \text { for some integer } \left.a \text { with } 0 \leqq a<m / M_{2^{u} \beta}\right\} \\
& -\# \bigcup_{\substack{0 \leq b<d \\
\lambda=0,1}}\left(D(m)_{\left(l-1, r^{n / 4}-1, l^{2} r^{b}+1\right)}^{m} \bigcup D(m)_{\left(l r^{\left.d^{\prime}-1, r^{n / 4}-1, l^{2} r^{b}+1\right)}\right)}^{m}\right), \\
t(3)= & \sum_{\beta \in D(n, 3)} \# D\left(M_{\beta}\right)-1, \\
t(4)= & \sum_{\beta \in D(n, 3)} \# D\left(M_{\beta}\right)-\sum_{\beta \in D(n, 3)_{k+1}^{n}} \# D\left(M_{\beta}\right)_{l+1}^{m} .
\end{aligned}
$$

Then we have:
Theorem 2.1 ([12; Theorem]). Let $G_{1}, G_{2}, G_{3}$ and $G_{4}$ denote the groups of type I, II, III and IV respectively.
(1) $S K_{1}\left(Z\left[G_{1}\right]\right)=0$.
(2) $S K_{1}\left(Z\left[G_{2}\right]\right) \cong Z_{2}^{t(2)}$ if $d$ is an odd integer,
$S K_{1}\left(Z\left[G_{2}\right]\right) \cong \boldsymbol{Z}_{2}^{t^{\prime}(2)} \quad$ if $d$ is an even integer.
(3) $S K_{1}\left(Z\left[G_{3}\right]\right) \cong Z_{2}^{t(3)}$.
(4) $\quad S K_{1}\left(Z\left[G_{4}\right]\right) \cong \boldsymbol{Z}_{2}^{(4)}$.

By Theorem 2.1, we get (1) and (2) of Theorem A. Let $G_{2}^{1}$ be a group $G_{2}$ such that $d$ is odd. At first, we determine the group $G_{2}^{1}$ satisfying $S K_{1}\left(Z\left[G_{2}^{1}\right]\right)=0$. Put

$$
\mathscr{T}_{+}=\left\{(\alpha, \beta) \mid \beta \in D(v)_{k-1}^{v}, \alpha \in D\left(M_{2^{u} \beta}\right),\right.
$$

$$
\left(\alpha+a M_{2^{u} \beta}\right)\left(l-1, r^{n / 4}-1\right) \equiv 0(m)
$$

$$
\text { for some integer } \left.a \text { with } 0 \leqq a<m / M_{2_{\beta} \beta}\right\} \text {, }
$$

and

$$
\mathscr{T}_{-}=\left\{(\alpha, v) \mid \alpha \in \bigcup_{\substack{0 \leq b<d \\ \lambda=0,1}} D(m)_{\left(l-1, r^{n / 4}-1, l^{\lambda} r^{b}+1\right)}^{m}\right\}
$$

By [12; §3], $t(2)$ the 2-rank of $S K_{1}\left(Z\left[G_{2}^{1}\right]\right)$ is calculated by

$$
t(2)=\# \mathscr{T}_{+}-\# \mathscr{T}_{-} .
$$

It is easy to see that $\mathscr{T}_{-}$is a subset of $\mathscr{T}_{+}$. Suppose that $t(2)=0$. Then it is necessary that $D(v)_{k-1}^{v}=\{v\}$. In fact, if there exists an element $\beta$ of $D(v)_{k-1}^{v}$ which is different from $v$, we see that the ordered pair of numbers $\left(M_{2^{u_{\beta}}}, \beta\right)$ is in $\mathscr{T}_{+}$, but is not in $\mathscr{T}_{-}$. Hence, if $\beta$ in $D(v)$ satisfies $\beta(k-1) \equiv 0(v)$, it must be equal to $v$. Thus we have $(k-1, v)=1$. Since $k^{2} \equiv 1 \quad(n)$ and $k \equiv-1 \quad\left(2^{u}\right)$, it holds that $k \equiv-1$ ( $n$ ). Since $d$ is a divisor of $k-1$ and $d$ is odd , by [12; Observation 3.1] ( $k-1, v$ ) is divisible by $d$. Hence we have $d=1$, thereby $r \equiv 1(m)$. By using $(n(r-1), m)=1$, we get $m=1$, that is, $A$ is equal to the identity element of $G_{2}^{1}$. Thus if $S K_{1}\left(Z\left[G_{2}^{1}\right]\right)=0, G_{2}^{1}$ must be isomorphic to a group of order $2 n$ which is generated by the elements of the form $B$ and $R$, and which has relations:

$$
B^{n}=1, R^{2}=B^{n / 2}, R B R^{-1}=B^{-1}
$$

where $n$ is a number of the form $2^{u} v$ for some $u \geqq 2,(v, 2)=1$, $v \geqq 1$. Conversely, we can easily check that $S K_{1}$ for this group vanishes. By putting $t=n / 4$, we have (3) of Theorem A.

Let $G_{2}^{0}$ be a group $G_{2}$ such that $d$ is even. Next, we determine the group $G_{2}^{0}$ satisfying $S K_{1}\left(Z\left[G_{2}^{0}\right]\right)=0$. Since $d$ is even, we have $m>1$. Put

$$
\begin{aligned}
\mathscr{T}_{+}^{\prime}=\{ & (\alpha, \beta) \mid \beta \in D(v)_{k-1}^{v}, \alpha \in D\left(M_{2^{u} \beta}\right), \\
& \left(\alpha+a M_{2^{u} \beta}\right)\left(l-1, r^{n / 4}-1\right) \equiv 0(m) \text { or } \\
& \left(\alpha+a M_{2^{u} \beta}\right)\left(l r^{d^{\prime}}-1, r^{n / 4}-1\right) \equiv 0(m) \\
& \text { for some integer } \left.a \text { with } 0 \leqq a<m / M_{2^{u} \beta}\right\},
\end{aligned}
$$

and

$$
\mathscr{T}_{-}^{\prime}=\left\{(\alpha, v) \mid \alpha \in \bigcup_{\substack{0 \leq b<d \\ \lambda=0,1}}\left(D(m)_{\left(l-1, r^{n / 4}-1, l^{\lambda} r^{b}+1\right)}^{m} \bigcup D(m)_{\left(l r^{\left.d^{\prime}-1, r^{n / 4}-1, l^{\lambda} b+1\right)}\right.}^{m}\right)\right\}
$$

By [12; §3], $t^{\prime}(2)$ the 2-rank of $S K_{1}\left(Z\left[G_{2}^{0}\right]\right)$ is calculated by

$$
t^{\prime}(2)=\# \mathscr{T}_{+}^{\prime}-\# \mathscr{T}_{-}^{\prime} .
$$

It is easy to see that $\mathscr{T}_{-}^{\prime}$ is a subset of $\mathscr{T}_{+}^{\prime}$. Then by the same argument as before, we have $D(v)_{k-1}^{v}=\{v\}$ and $(k-1, v)=1$. Since $k^{2} \equiv 1(n)$ and $k+1 \equiv 0\left(2^{u}\right)$, it holds that $k \equiv-1(n)$. Since $d$ is even, by [12; Observation 3.1], $d^{\prime}=d / 2$ is a divisor of $(k-1, v)$. Hence, we have $d=2$, thereby $r \not \equiv 1$ $(m)$ and $r^{2} \equiv 1(m)$. Now we claim that $r \equiv-1(m)$. In fact, since $(r+1)$ $(r-1) \equiv 0(m)$ and $(r-1, m)=1$, it holds that $r+1 \equiv 0(m)$ or $m=1$. However, it must hold $r \equiv-1(m)$ because $m>1$. Therefore, we have

$$
\left(l r^{d^{\prime}}-1, r^{n / 4}-1\right)=\left(l+1,(-1)^{n / 4}-1\right)
$$

Thus, for $\# \mathscr{T}_{+}^{\prime}=\# \mathscr{T}_{-}^{\prime}$, it is necessary that

$$
\begin{aligned}
& \#\left\{\alpha \in D(m) \mid \alpha\left(l-1,(-1)^{n / 4}-1\right) \equiv 0(m)\right. \\
&\text { or } \left.\alpha\left(l+1,(-1)^{n / 4}-1\right) \equiv 0(m)\right\} \\
&= \bigcup_{\substack{b=0,1 \\
\lambda=0,1}}\left(D(m)_{\left(l-1,(-1)^{n / 4}-1,(-1)^{b} l^{\lambda}+1\right)}^{m} \bigcup D(m)_{\left(l+1,(-1)^{m / 4}-1,(-1)^{b} l+1\right)}^{m}\right) .
\end{aligned}
$$

However, we can easily check that this formula always holds. Thus, if $S K_{1}\left(Z\left[G_{2}^{0}\right]\right)=0, G_{2}^{0}$ must be isomorphic to a group of order $2 n$ which is generated by the elements of the form $A, B$ and $R$, and which has relations:

$$
\begin{aligned}
& A^{m}=B^{n}=1, B A B^{-1}=A^{-1} \\
& R^{2}=B^{n / 2}, R A R^{-1}=A^{l}, R B R^{-1}=B^{-1}
\end{aligned}
$$

where $m, n$ and $l$ satisfy the following conditions:

$$
\begin{aligned}
& m>1,(n, m)=1, l^{2} \equiv 1(m) \\
& n=2^{u} v(u \geqq 2,(v, 2)=1, v \geqq 1)
\end{aligned}
$$

Conversely, we can easily check that $S K_{1}$ for this group vanishes. Now, we put $t=n / 4$. Since $l^{2} \equiv 1(m)$, there exist two integers $m_{1}$ and $m_{2}$ such that $m=m_{1} m_{2},\left(m_{1}, m_{2}\right)=1, l \equiv-1\left(m_{1}\right)$, and $l \equiv 1\left(m_{2}\right)$. Conversely if we write $m=m_{1} m_{2}$ where $\left(m_{1}, m_{2}\right)=1$, there exists an integer $l$ uniquely modulo $m$ such that $l \equiv-1\left(m_{1}\right)$ and $l \equiv 1\left(m_{2}\right)$. We denote this group by $\mathbf{Q}\left(8 t, m_{1}, m_{2}\right)$ (This notation is based on [11]). Thus we get (4) of

Theorem A.
Next, we determine the group $G_{3}$ satisfying $S K_{1}\left(Z\left[G_{3}\right]\right)=0$. Assume that

$$
t(3)=\sum_{\beta \in D(n, 3)} \# D\left(M_{\beta}\right)-1=0
$$

Since $\# D\left(M_{\beta}\right) \geqq 1$ for every $\beta \in D(n, 3)$, it is necessary that $\# D(n, 3)=1$. Hence, $n$ must be 3 , thereby $d$ is 1 or 3 . However, if $d=3, n / d$ is not divisible by 3 . Hence $d$ must be equal to 1 , thereby $r \equiv 1(m)$. By using ( $n(r-1), m)=1$, we have $m=1$, that is, $A$ is equal to the identity element of $G_{3}$. Thus, if $S K_{1}\left(Z\left[G_{3}\right]\right)=0, G_{3}$ must be isomorphic to a group of order 24 which is generated by the elements of the form $B, P$ and $Q$, and which has relations:

$$
B^{3}=1, P^{2}=Q^{2}=(P Q)^{2}, B P B^{-1}=Q, B Q B^{-1}=P Q .
$$

This group is the binary tetrahedral group T*. Conversely, we can easily see that $S K_{1}\left(Z\left[\mathbf{T}^{*}\right]\right)=0$. This proves (5) of Theorem A.

Next, we determine the group $G_{4}$ satisfying $S K_{1}\left(Z\left[G_{4}\right]\right)=0$. Suppose that

$$
t(4)=\sum_{\beta \in D(n, 3)} \# D\left(M_{\beta}\right)-\sum_{\beta \in D(n, 3)_{k+1}^{n}} \# D\left(M_{\beta}\right)_{l+1}^{m}=0
$$

Then it is necessary that $D(n, 3)=D(n, 3)_{k+1}^{n}$. In fact, if there exists an element $\beta_{0}$ of $D(n, 3)-D(n, 3)_{k+1}^{n}$, since $\# D\left(M_{\beta_{0}}\right) \geqq 1$, we have $t(4) \neq 0$. Hence, for every element $\beta$ in $D(n, 3)$, it must hold that $\beta(k+1) \equiv 0$ (n). In particular, we have $3(k+1) \equiv 0(n)$. Thus $k$ must satisfy $k+1 \equiv 0(n / 3)$. We claim that $k \equiv-1(n)$. In fact, if $k$ is congruent to $n / 3-1$ or $2 n / 3-1$ modulo $n$, the conditions $k+1 \equiv 0(3)$ and $n \equiv 0(3)$ imply $n \equiv 0$ (9), but it is a contradiction to the condition $k^{2} \equiv 1(n)$. Therefore we have

$$
r^{k-1} \equiv r^{n-2} \equiv r^{n} \equiv 1(m)
$$

which implies $d$ is a divisor of $(n-2, n)$. Since a group $G_{4}$ has odd $n$, we have $d=1$. By the same argument as above, we have $m=1$, that is, $A$ is equal to the identity element of $G_{4}$. Thus if $S K_{1}\left(Z\left[G_{4}\right]\right)=0, G_{4}$ must be a group of order $16 n$ which is generated by the elements of the
form $B, P, Q$ and $R$, and which has relations:

$$
\begin{aligned}
& B^{n}=1, P^{2}=Q^{2}=(P Q)^{2}=R^{2} \\
& B P B^{-1}=Q, B Q B^{-1}=P Q, R P R^{-1}=Q P \\
& R Q R^{-1}=Q^{-1}, R B R^{-1}=B^{-1}
\end{aligned}
$$

where $n$ is divisible by 3 , but is not divisible by 2 . This group is the generalized binary octahedral group $\mathbf{O}^{*}(48 t)$. Conversely, we can easily check that $S K_{1}\left(Z\left[O^{*}(48 t)\right]\right)=0$. This proves (6) of Theorem A.

Next, we consider the case that $G$ is non-solvable.
Lemma 2.2 ([16; 6.3.1 Theorem]). Let $G$ be a finite non-solvable group. If $G$ has a fixed point free representation, then $G$ is one of the following two types.

Type V. $\quad G=K \times S L(2,5)$ where $K$ is a solvable fixed point free group of type I in Appendix and order prime to 30.

Type VI. $G=<G_{5}, S>$ where $G_{5}=K \times S L(2,5)$ is a normal subgroup of index 2 and type $\mathrm{V}, S^{2}=-1 \in S L(2,5), S L S^{-1}=\left(\begin{array}{cc}0 & -1 \\ 2 & 0\end{array}\right) L\left(\begin{array}{cc}0 & -1 \\ 2 & 0\end{array}\right)^{-1}$ for $L \in S L(2,5)$, and $S$ normalizes $K$.

Let $G$ be a finite group of type V or VI. For an odd prime $p$, since $p$-Sylow subgroups of $G$ are cyclic, $S K_{1}(Z[G])_{(p)}=0$. Hence by [7; Theorem 3], $S K_{1}(Z[G])$ is generated by induciton from 2-elementary subgroups of $G$, that is, $S K_{1}(Z[G])=0$ if and only if $G$ has not a subgroup which is isomorphic to $\Gamma \times S_{2}$ where $\Gamma$ is a cyclic group of order prime to 2 and $S_{2}$ is a 2-group. In these cases, $S K_{1}(Z[G])=0$ if and only if $G$ has not a subgroup of the form $\Gamma \times \mathbf{Q}_{8}$ (see [5]). Hence $K$ must be $\{1\}$ which proves (7) and (8) of Theorem A.

## 3. $G$ - $h$-cobordisms between $G$-homotopy spheres

Let $W h(G)$ be the Whitehead group of $G, L_{m}^{s}(G)$ and $L_{m}^{h}(G)$ the Wall groups (for the Wall groups, see [2], [14]). $Z[G]$ is the integral group ring with involution - defined by $\overline{\Sigma a_{g} g}=\Sigma a_{g} g^{-1}$ where $a_{g} \in Z$ and $g \in G$. For a matrix ( $x_{i j}$ ) with coefficients in $\boldsymbol{Z}[G],\left(\overline{x_{i j}}\right)$ is defined by $\left(\overline{x_{j i}}\right)$. Then $W h(G)$ has the induced involution also denoted by -. We define a subgroup $\tilde{A}_{m}(G)$ of $W h(G)$ by

$$
\tilde{A}_{m}(G)=\left\{\tau \in W h(G) \mid \bar{\tau}=(-1)^{m} \tau\right\}
$$

and put

$$
A_{m}(G)=\tilde{A}_{m}(G) /\left\{\tau+(-1)^{m} \bar{\tau} \mid \tau \in W h(G)\right\} .
$$

Let $c: A_{2 n+1}(G) \rightarrow L_{2 n}^{s}(G)$ be the map in the Rothenberg exact sequence

$$
\cdots \rightarrow A_{2 n+1}(G) \xrightarrow{c} L_{2 n}^{s}(G) \xrightarrow{d} L_{2 n}^{h}(G) \rightarrow \cdots,
$$

and $\tilde{c}: \tilde{A}_{2 n+1}(G) \rightarrow L_{2 n}^{s}(G)$ the map determing $c$ (for this exact sequence, see [8; Proposition 4.1]).

Proposition 3.1. Let $G$ be a finite group such that $S K_{1}(Z[G])=0$. Then the following hold:
(1) If $X$ is a free $G$-homotopy sphere of dimension $2 n-1 \geqq 5$, any $G$-h-cobordism $W$ between $X$ and itself must be $G$-diffeomorphic to $X \times I$.
(2) If $S(V)$ and $S\left(V^{\prime}\right)$ are free linear $G$-spheres of dimension $2 n-1 \geqq 5$, any $G$-h-cobordism $W^{\prime}$ between $S(V)$ and $S\left(V^{\prime}\right)$ must be $G$-diffeomorphic to $S(V) \times I$.

Proof. (1) In the case $|G| \leqq 2$, since it holds that $W h(G)=0$, the conclusion follows from the $s$-cobordism theorem. Our proof will be done under $|G| \geqq 3$. Let $W$ be a $G$ - $h$-cobordism between $X$ and itself, with $\operatorname{dim} W=2 n \geqq 6$. To distinguish the inclusions of $X$ to $W$, we put $\partial W=X \amalg X^{\prime}$, where $X^{\prime}$ is a copy of $X . \quad$ Let $i: X \rightarrow W$ and $i^{\prime}: X^{\prime} \rightarrow W$ be the natural inclusion maps. Let $r$ be a $G$-homotopy inverse of $i$. Since the order of $G$ is greater than or equal to 3 and $G$ acts freely on a homotopy sphere $X$ with $\operatorname{dim} X \geqq 5$, any $G$-self-homotopy equivalence of $X$ is $G$-homotopic to the identity map. Hence, we have

$$
\tau\left(r \circ i^{\prime}\right)=\tau(i d)=0 .
$$

On the other hand,

$$
\begin{aligned}
\tau\left(r \circ i^{\prime}\right) & =\tau(r)+r_{*} \tau\left(i^{\prime}\right) \\
& =-r_{*} \tau(i)+r_{*} \tau\left(i^{\prime}\right) \\
& =r_{*}\left(\tau\left(i^{\prime}\right)-\tau(i)\right) .
\end{aligned}
$$

Thus we have $\tau\left(i^{\prime}\right)=\tau(i)$, that is,

$$
\tau(W, X)=\tau\left(W, X^{\prime}\right)
$$

By the duality theorem ([6; p. 394]), we also get

$$
\tau\left(W, X^{\prime}\right)=-\overline{\tau(W, X)}
$$

Hence by these formulae, we see that $\tau=-\bar{\tau}$, that is, $\tau$ is an element of $\tilde{A}_{2 n+1}(G)$.

Since $G$ has periodic cohomolgy, $\tilde{A}_{2 n+1}(G)$ is isomorphic to $S K_{1}(Z[G])$ by [9; Theorem 3]. Hence we have $\tilde{A}_{2 n+1}(G)=0$, thereby $\tau=0$.
(2) Let $C$ be a cyclic subgroup of $G$. By Theorem 1.2, $\operatorname{res}_{c} V=\operatorname{res}_{c} V^{\prime}$ as real $C$-modules. Thus $V=V^{\prime}$ as real $G$-modules, and then $S\left(V^{\prime}\right)$ is $G$-diffeomorphic to $S(V)$. Since $S K_{1}(Z[G])=0$, the conclusion now follows from (1) of this proposition.

Proof of Examples. Example B follows from Theorem A and Proposition 3.1 immediately. By [10], if a finite group $G$ whose 2-Sylow subgroups are quaternionic acts freely on spheres, its dimension must be $4 n-1(n \in N)$. Hence, if a finite group $G$ can act freely on spheres of dimension $4 n+1$, the 2 -Sylow subgroups of $G$ are cyclic. Thus $G$ must be of Type I in Appendix, thereby $S K_{1}(Z[G])=0$, which proves Example C.

In [13], we studied $G$ - $h$-cobordisms between $G$-homotopy spheres and obtained the following results:

Theorem 3.2 ([13; Theorem A]). Let $G$ be a finite group, and $X$ a free $G$-homotopy sphere of dimension $2 n-1 \geqq 5$. Then the following (1) and (2) are equivalent.
(1) Any $G$-h-cobordism $W$ between $X$ and itself must be G-diffeomorphic to $X \times I$.
(2) $\operatorname{ker} \tilde{c}$ is trivial.

Corollary 3.3 ([13; Corollary B]). Suppose ker $\tilde{c}=0$. Let $S(V)$ and $S\left(V^{\prime}\right)$ be free linear $G$-spheres of dimension $2 n-1 \geqq 5$. Then a $G$-h-cobordism $W$ between $S(V)$ and $S\left(V^{\prime}\right)$ must be $G$-diffeomorphic to $S(V) \times I$.

Theorem 3.2 is shown by using surgery theory. Corollary 3.3 is an immediate consequence of Theorem 3.2. Since by [9; Theorem 3] $S K_{1}(Z[G]) \cong \tilde{A}_{2 n+1}(G)$ for a periodic group $G$, Proposition 3.1 is a special case of Theorem 3.2 and Corollary 3.3. Moreover, as in [13], there exists a finite group $G$ such that $S K_{1}(Z[G]) \neq 0$ and $\operatorname{ker} \tilde{c}=0$. For example, let $p$ be an odd prime, $q$ a prime such that $q \geqq 5$. Let $G$ be $\mathbf{Q}_{8} \times \boldsymbol{Z}_{p}, \mathbf{T}^{*} \times \boldsymbol{Z}_{q}$, or $\mathbf{O}^{*} \times \boldsymbol{Z}_{q}$, where $\mathbf{Q}_{8}, \mathrm{~T}^{*}$, and $\mathbf{O}^{*}$ denote the quaternionic group, the binary tetrahedral group, and the binary octahedral group
respectively. Then we see that $S K_{1}(Z[G]) \cong \boldsymbol{Z}_{2}$ and any $G$ - $h$-cobordism $W$ between a free $G$-homotopy sphere $X$ of dimension $4 n-1 \geqq 7$ and itself must be $G$-diffeomorphic to $X \times I$, because $\operatorname{ker} \tilde{c}=0$.

## 4. Proof of Theorem $D$

Let $G$ be a compact Lie group of positive dimension which can act freely on a sphere. Then by [3; p. 153, Theorem 8.5], $G$ must be isomorphic to $S^{1}$, $S^{3}$ or $N S^{1}$ the normalizer of $S^{1}$ in $S^{3}$. If $G$ is $S^{1}$, the dimension of a sphere on which $G$ acts freely is $2 n-1(n \geqq 1)$. If $G$ is $N S^{1}$ or $S^{3}$, it is $4 n-1(n \geqq 1)$ because $G$ has a subgroup which is isomorphic to $\mathbf{Q}_{8}$. Now we recall the equivariant Whitehead group which is defined by S. Illman. By [4; Corollary 2,8],

$$
\begin{array}{lll}
W h_{S^{1}}\left(X^{m}\right) \cong W h(1)=0 & \text { where } & m=2 n-1 \geqq 7 \\
W h_{N S^{1}}\left(X^{m}\right) \cong W h\left(Z_{2}\right)=0 & \text { where } & m=4 n-1 \geqq 7, \\
W h_{S^{3}}\left(X^{m}\right) \cong W h(1)=0 & \text { where } & m=4 n-1 \geqq 11 .
\end{array}
$$

Thus ( $W ; X, X^{\prime}$ ) is a $G$-s-cobordism in the sense of [1]. The conclusion now follows from the conditions about the dimension of the homotopy sphere by using[1; Theorem 1].

## 5. Appendix

Let $G$ be a finite solvable group. Then $G$ has a fixed point free complex representation if and only if $G$ is of type I, II, III, IV below, with the additional condition: if $d$ is the order of $r$ in the multiplicative group of residues modulo $m$, of integers prime to $m$, then $n / d$ is divisible by every prime divisor of $d$.

Type I. A group of order $m n$ that is generated by the elements of the from $A$ and $B$, and that has relations:

$$
A^{m}=B^{n}=1, B A B^{-1}=A^{r}
$$

where $m, n$ and $r$ satisfy the following conditions:

$$
m \geq 1, n \geq 1,(n(r-1), m)=1, r^{n} \equiv 1(m)
$$

Type II. A group of order $2 m n$ that is generated by the elements of the form $A, B$ and $R$, and that has relations:

$$
R^{2}=B^{n / 2}, R A R^{-1}=A^{l}, R B R^{-1}=B^{k}
$$

in addition to the relations in I, where $m, n, r, l$ and $k$ satisfy the following conditions:

$$
\begin{aligned}
& l^{2} \equiv r^{k-1} \equiv 1(m), k \equiv-1\left(2^{u}\right) \\
& n=2^{u} v(u \geqq 2,(v, 2)=1), k^{2} \equiv 1(n)
\end{aligned}
$$

in addition to the conditions in I.
Type III. A group of order $8 m n$ that is generated by the elements of the form $A, B, P$ and $Q$, and that has relations:

$$
\begin{aligned}
& P^{2}=Q^{2}=(P Q)^{2}, A P=P A, A Q=Q A \\
& B P B^{-1}=Q, B Q B^{-1}=P Q
\end{aligned}
$$

in addition to the relations in I , where $m, n$ and $r$ satisfy the following conditions:

$$
n \equiv 1(2), n \equiv 0(3)
$$

in addition to the conditions in I.
Type IV. A group of order $16 m n$ that is generated by the elements of the form $A, B, P, Q$ and $R$, and that has relations:

$$
\begin{aligned}
& R^{2}=P^{2}, R P R^{-1}=Q P, R Q R^{-1}=Q^{-1} \\
& R A R^{-1}=A^{l}, R B R^{-1}=B^{k}
\end{aligned}
$$

in addition to the relations in III, where $m, n, r, k$ and $l$ satisfy the following conditions:

$$
l^{2} \equiv r^{k-1} \equiv 1(m), k \equiv-1(3), k^{2} \equiv 1(n)
$$

in addition to the conditions in III.
