# FERMAT'S THEOREM FOR ALGEBRAS 

Gordon L. Walker

1. Introduction. Let $A$ be an algebra over the field $F$ and let $F\left[x_{1}, \cdots, x_{n}\right]$ be a free algebra over $F$ generated by indeterminates $x_{1}, \cdots, x_{n}$; then

$$
f\left(x_{1}, \cdots, x_{n}\right) \in F\left[x_{1}, \cdots, x_{n}\right]
$$

is a polynomial identity for $A$ if $f \not \equiv 0$ and $f\left(a_{1}, \cdots, a_{n}\right)=0$ for all $a_{1} \in A$. Some of the recent investigations [2;3] of polynomial identities have been concerned with those that are linear in each indeterminate, and for certain algebras all such polynomial identities are known.

In the following we obtain other information on polynomial identities by investigating those in a single indeterminate. Our results provide a generalization of the Fermat theorem when this is formulated as: $x^{p^{n}}-x$ is a polynomial identity for the field of $p^{n}$ elements. Other generalizations have been given [4] that determine the least common multiple of the orders of the nonsingular elements of a total matrix algebra over a finite field.
2. An ideal of polynomial identities. If $A$ is an algebra over $F$, and $x$ an indeterminate, let $d(A)$ be the set of all $f(x)$ in $F[x]$ such that $f(a)=0$ for all $a \in A$. We then clearly have:

Lemma 1. $d(A)$ is a principal ideal in $F[x]$.
Theorem l. If $A$ is a total matrix algebra of order $m^{2} \operatorname{over} \operatorname{GF}\left(p^{n}\right)$, then $\ell(A)$ is the principal ideal generated by $f\left(m, p^{n}, x\right)$, the monic least common multiple of all polynomials of degree $m$ in $G F\left(p^{n}\right)[x]$.

Proof. $f\left(m, p^{n}, x\right) \in d(A)$ since it is divisible by the minimal polynomial of every element of $A$. If $g(x) \in \mathcal{d}(A)$ then it is a multiple of $f\left(m, p^{n}, x\right)$, for if $h(x)$ is any monic polynomial of degree $m$ in $G F\left(p^{n}\right)[x]$ there exists $a \in A$ so that $h(x)$ is the minimal polynomial of $a$ over $G F\left(p^{n}\right)[5, \mathrm{p} .148]$.

To extend this result we use:
Received March 15, 1953.
Pacific J. Math. 4 (1954), 317-320

Lemma 2. If $A$ is a subalgebra of $B$ then $d(A) \supseteq d(B)$.
Lemma 3. If $A_{1}, A_{2}$ are algebras over $F$ then

$$
d\left(A_{1} \oplus A_{2}\right)=d\left(A_{1}\right) \cap d\left(A_{2}\right) .
$$

Proof. Lemma 2 is trivial, and this implies

$$
d\left(A_{1} \oplus A_{2}\right) \subseteq d\left(A_{1}\right) \cap d\left(A_{2}\right) .
$$

If $a \in A_{1} \oplus A_{2}$ then

$$
a=a_{1}+a_{2},
$$

where $a_{1} a_{2}=0$ and $a_{i} \in A_{i}$, so that

$$
a^{k}=a_{1}^{k}+a_{2}^{k}
$$

for all integers $k$. Thus

$$
f(a)=f\left(a_{1}\right)+f\left(a_{2}\right)
$$

for all $f(x) \in F[x]$, and

$$
d\left(A_{1}\right) \cap d\left(A_{2}\right) \subseteq d\left(A_{1} \oplus A_{2}\right) .
$$

We now have:
Theorem 2. If $A=A_{1} \oplus \ldots \oplus A_{k}$, where each $A_{i}$ is a total matrix algebra of order $m_{i}^{2}$ over $G F\left(p^{n}\right)$, and

$$
m_{1} \leq m_{2} \leq \cdots \leq m_{k},
$$

then $d(A)$ is the principal ideal generated by $f\left(m_{k}, p^{n}, x\right)$.
3. A determination of $f\left(m, p^{n}, x\right)$. The following theorem with Theorem 1 becomes the Fermat theorem in case $m=1$.

Theorem 3. $f\left(m, p^{n}, x\right)=\left(x^{p^{n}}-x\right)\left(x^{p^{2 n}}-x\right) \cdots\left(x^{p^{m n}}-x\right)$.
This follows by induction from:
Lemma 4. $f\left(m, p^{n}, x\right)=\left(x^{p^{m n}}-x\right) f\left(m-1, p^{n} ; x\right)$.

To show this we let $\mu[g(x), h(x)]$, where $g(x), h(x) \in G F\left(p^{n}\right)[x]$, denote the multiplicity (including zero) of $g(x)$ as a factor of $h(x)$; because the unique factorization property holds, we have only to show

$$
\begin{equation*}
\mu\left[g_{k}(x), f\left(m, p^{n}, x\right)\right]=\mu\left[g_{k}(x), x^{p^{m n}}-x\right]+\mu\left[g_{k}(x), f\left(m-1, p^{n}, x\right)\right] \tag{1}
\end{equation*}
$$

for all irreducible monic polynomials $g_{k}(x)$ of degree $k \leqq m$ in $G F\left(p^{n}\right)$ [ $\left.x\right]$. But

$$
\mu\left[g_{k}(x), f\left(m_{i}, p^{n}, x\right)\right] \text { is } \mu\left[g_{k}(x), f\left(m-1, p^{n}, x\right)\right]
$$

when $k$ does not divide $m$, and is $\mu\left[g_{k}(x), f\left(m-1, p^{n}, x\right)\right]+1$ when $k$ divides $m$. Thus (1) holds, since $x^{p^{m n}}-x$ is the product of all $g_{k}(x)$ such that $k$ divides $m$ [1, p. 17].
4. Further results concerning $d(A)$. The preceding results together with the structure theorem for semi-simple algebras imply:

Theorem 4. If $A$ is a semi-simple algebra of characteristic $p$, and the simple components of $A$ have orders $m_{1}^{2}, \cdots, m_{k}^{2}$ over their centers $G F\left(p^{n_{1}}\right), \ldots$, $G F\left(p^{n_{k}}\right)$, respectively, then $d(A)$ is the principal ideal generated by the least common multiple of

$$
f\left(m_{1}, p^{n_{1}}, x\right), \cdots, f\left(m_{k}, p^{n_{k}}, x\right)
$$

A further extension is provided by:
Theorem 5. If $A$ is an algebra over $F$ with radical $N$, if

$$
d(A-N)=(f), f \in F[x],
$$

and if $l(N)=\left(x^{r}\right)$, that is, index $N=r$, then

$$
\left(g_{1}\right) \supseteq d(A) \supseteq\left(g_{2}\right),
$$

where $g_{1}$ is the least common multiple of $x^{r}$ and $f(x)$, and $g_{2}=[f(x)]^{r}$.
Proof. From $f(x) \in d(A-N)$ we deduce $f(a) \in N$ for every $a \in A$, so

$$
d(A) \supseteq\left(g_{2}\right) .
$$

From Lemma 2 we have both $d(A-N)$ and $d(N)$ including $d(A)$, so their intersection $\left(g_{1}\right)$ includes $d(A)$.

Remark. The following example shows that the bounds on $d(A)$ in Theorem 5 cannot be improved without further hypothesis. If $e_{i j}(i, j=1,2)$ are matrix units, and $F=G F(2)$, let $A_{1}$ be the algebra with basis $e_{11}, e_{12}$ over $F$, and let $A_{2}$ be the algebra with basis $e_{11}, e_{12}, e_{22}$ over $F$. Both algebras have radicals of index 2 , and $f(x)=x^{2}-x$; but

$$
d\left(A_{1}\right)=\left(g_{1}\right), \quad d\left(A_{2}\right)=\left(g_{2}\right),
$$

where

$$
g_{1}=x^{3}-x^{2}, g_{2}=x^{4}-x^{2}=\left(x^{2}-x\right)^{2},
$$

so that $\left(g_{1}\right) \neq\left(g_{2}\right)$.
