#### Abstract

We consider step and soft skew products over the Bernoulli shift which have an $m$-dimensional closed manifold as a fiber. It is assumed that the fiber maps Hölder continuously depend on a point in the base. We prove that, in the space of skew product maps with this property, there exists an open domain such that maps from this open domain have dense sets of periodic points that are attracting and repelling along the fiber. Moreover, robust properties of invariant sets of diffeomorphisms, including the coexistence of dense sets of periodic points with different indices, are obtained.

## 1. Introduction

In [1], Gorodetski and Ilyashenko studied certain properties of skew product maps over the Bernoulli shift and the SmaleWilliams solenoid, with a fiber $S^{1}$. They provided an open set in the space of these skew products such that each mapping from this open set has a dense set of periodic orbits that are attracting and repelling along the fiber.

In this paper, we improve their results to skew product maps which have an $m$-dimensional closed manifold $M$ as a fiber. Moreover, we prove that small perturbations of these skew products in the space of all diffeomorphisms have partially hyperbolic invariant sets. Also, they admit dense subsets of periodic points with different indices.

To be more precise, let us describe skew product maps which apply here in detail.

From now on, the ambient fiber space $M$ will be an $m$-dimensional closed manifold and its metric is geodesic distance and the measure is the Riemannian volume.

Consider diffeomorphisms $f_{i}, i=1, \ldots, k$, defined on $M$. The iterated function system $\mathscr{F}\left(M ; f_{1}, \ldots, f_{k}\right)$ is the semigroup generated by $f_{1}, \ldots, f_{k}$, that is, the set of all maps $f_{t_{j}} \circ \cdots \circ f_{t_{1}}$, where $t_{j}, \ldots, t_{1} \in\{1, \ldots, k\}$.

The $\mathscr{F}$-orbit of $x \in M$ is the set of points $f_{t_{i}} \circ \cdots \circ f_{t_{1}}(x)$, $t_{j} \geq 0$.

An iterated function system $F\left(M ; f_{1}, \ldots, f_{k}\right)$ is called minimal if each closed subset $A$ with $f_{i}(A) \subset A$, for all $i$, is empty or coincides with $M$. This means that $\mathscr{F}$-orbit of each $x \in M$ is dense in $M$.

Let $f_{i}, i=0,1$, be diffeomorphisms of $M$. A step skew product over the Bernoulli shift $\sigma: \Sigma^{2} \rightarrow \Sigma^{2}$ is defined by

$$
\begin{equation*}
F: \Sigma^{2} \times M \longrightarrow \Sigma^{2} \times M ; \quad(\omega, x) \longrightarrow\left(\sigma \omega, f_{w_{0}}(x)\right) \tag{1}
\end{equation*}
$$

where $\Sigma^{2}$ is the space of two-sided sequences of 2 symbols $\{0,1\}$. Consider the following standard metric on $\Sigma^{2}$ :

$$
\begin{equation*}
d\left(\omega, \omega^{\prime}\right)=2^{-n} \tag{2}
\end{equation*}
$$

where $n=\min \left\{|k| ; \omega_{k} \neq \omega_{k}^{\prime}\right\}$ and $\omega, \omega^{\prime} \in \Sigma^{2}$.
Let us note that an iterated function system can be embedded in a single dynamical system, the skew product $F$ of the form (1), such that the action orbits of the iterated function system $\mathscr{F}$ with generators $f_{i}$ coincide with the projections of positive semitrajectories of the skew product $F$ onto the fiber along the base.

A soft skew product over the Bernoulli shift is a map

$$
\begin{equation*}
G: \Sigma^{2} \times M \longrightarrow \Sigma^{2} \times M ; \quad(\omega, x) \longrightarrow\left(\sigma \omega, g_{\omega}(x)\right) \tag{3}
\end{equation*}
$$

where the fiber maps $g_{\omega}$ are diffeomorphisms of the fiber into itself.

We would like to mention that in contrast to step skew products, the fiber maps of soft skew products depend on the whole sequence $\omega$.

Skew products play an important role in the theory of dynamical systems. Many properties observed for these products appear to persist as properties of diffeomorphisms [1, 2].

Let $w$ be a finite segment on the alphabets $\{0,1\}$. We denote by $\{\cdots \mid w \cdots\}$ an arbitrary infinite sequence $\omega$ in which $w$ occurs starting from the zeroth position. In a similar way, we introduce the notation $\{\cdots w \mid \cdots\}$ and $\{\cdots w$ | $\left.w^{\prime} \cdots\right\}$. We also denote by $|w|$ the length of $w$.

We recall that a map $F$ is called topologically mixing if for each nonempty open sets $U, V \in \Sigma^{2} \times M, F^{n}(U)$ intersects with $V$ for all large enough $n \in \mathbb{N}$.

For a diffeomorphism $f$ of $M$, a compact $f$-invariant set $\Lambda$ has a dominated splitting if

$$
\begin{equation*}
T_{\Lambda} M=E_{1} \oplus \cdots \oplus E_{k} \tag{4}
\end{equation*}
$$

where each $E_{i}$ is nontrivial and $D f$-invariant for $1 \leq i \leq k$ and there exists an $m \in \mathbb{N}$ such that

$$
\begin{equation*}
\left\|\left.D f^{n}\right|_{E_{i}(x)}\right\|\left\|\left(\left.D f^{n}\right|_{E_{j}(x)}\right)^{-1}\right\| \leq \frac{1}{2}, \tag{5}
\end{equation*}
$$

for every $n \geq m, i>j$ and $x \in \Lambda$.
The set $\Lambda$ is partially hyperbolic if it has a dominated splitting

$$
\begin{equation*}
T_{\Lambda} M=E_{1} \oplus \cdots \oplus E_{k} \tag{6}
\end{equation*}
$$

and there exists some $n \in \mathbb{N}$ such that $D f^{n}$ either uniformly contracts $E_{1}$ or uniformly expands $E_{k}$.

We are now ready to state our main results. The first result describes the robust density of attracting and repelling periodic orbits along the fiber.

Theorem 1. There exist $C^{1}$ diffeomorphisms $f_{i}: M \rightarrow M$, $i=0,1$, and $C^{1}$-neighborhoods $U_{0}\left(f_{0}\right), U_{1}\left(f_{1}\right) \subset \operatorname{Diff}^{1}(M)$ such that for any $g_{0} \in U_{0}$ and $g_{1} \in U_{1}$, the periodic orbits of the step skew product $F$ of the form (1) with the fiber maps $g_{i}, i=0,1$, which are attracting (or repelling) along $M$, are dense in $\Sigma^{2} \times M$.

By applying the Hölder property, one can translate the properties of step skew products to the case of soft skew products.

Theorem 2. There exist diffeomorphisms $f_{0}$ and $f_{1}$ on anymdimensional closed manifold $M$, and $C^{2}$ neighborhoods $U_{0}\left(f_{0}\right)$, $U_{1}\left(f_{1}\right) \subset \operatorname{Diff}^{2}(M)$ such that, for each $C>1$ and $\alpha>0$, if a soft skew product map $G$ of the form (3) satisfies the following conditions:
(1) $g_{\omega} \in U_{\omega_{0}}$, for any $\omega \in \Sigma^{2}$,
(2) $d_{C^{1}}\left(g_{\omega}, g_{\omega^{\prime}}\right) \leq C\left(d_{\Sigma^{2}}\left(\omega, \omega^{\prime}\right)\right)^{\alpha}$, for $\omega, \omega^{\prime} \in \Sigma^{2}$,
(3) $L \cdot 2^{-\alpha}<1$,
then the periodic orbits of $G$ which are attracting (or repelling) along the fiber are dense in $\Sigma^{2} \times M$.

Now by using the smooth realizations of step skew products, we prove that the above properties are preserved under small perturbations of these products in the space of $C^{2}$ diffeomorphisms.

Theorem 3. Let $n$ and $m$ be positive integers with $n \geq m+$ 3 , $n \geq 5$, and $m \geq 1$. Suppose that $N$ is an $n$-dimensional closed manifold. Then there exists an open set $\mathscr{U} \subset \operatorname{Diff}^{2}(N)$ such that, for any $f \in \mathscr{U}$, there is a partially hyperbolic locally maximal invariant set $\Delta \subset N$ and two numbers $l_{1}$ and $l_{2}=l_{1}+$ $m$, such that the hyperbolic periodic orbits with stable manifolds of dimension $l_{i}$ are dense in $\Delta$.

## 2. Step Skew Products

This section is devoted to prove Theorem 1 . We will show that there exists an open set $\mathscr{U}$ in the space of step skew product maps of the form (1) such that, for any map $F \in \mathscr{U}$, the periodic orbits of $F$ which are attracting along $M$ are dense in $\Sigma^{2} \times M$. The same property holds for periodic orbits which are repelling along $M$.

First, let us recall some notations and definitions. We consider the iterations of step skew product map F. Clearly, for $n>0$

$$
\begin{align*}
& F^{n}(\omega, x)=\left(\sigma^{n} \omega, \bar{f}_{n}[w](x)\right) \\
& F^{-n}(\omega, x)=\left(\sigma^{-n} \omega, \bar{f}_{-n}[w](x)\right), \tag{7}
\end{align*}
$$

where $\bar{f}_{n}[\omega]=f_{\omega_{n-1}} \circ \cdots \circ f_{\omega_{0}}, \bar{f}_{-n}[\omega]=f_{\omega_{-n}}^{-1} \circ \cdots \circ f_{\omega_{-1}}^{-1}$, $\bar{f}_{0}[\omega]=$ id. A periodic orbit of a step skew product map $F$ is determined by its initial point ( $\omega, x$ ), where $x \in M$ and $\omega \in \Sigma^{2}$ is a periodic sequence

$$
\begin{equation*}
\omega=\cdots w w w \cdots=(w) \tag{8}
\end{equation*}
$$

with a finite zero-one segment $w=\left(w_{0} \cdots w_{n-1}\right)$. We say that a periodic orbit $((w), x)$ is attracting along $M$ if $\| D \bar{f}_{|w|}$ $[w](x) \|<1$ and is repelling along $M$ if $\left\|D \bar{f}_{|w|}[w](x)\right\|>1$.

From now on, the ambient $M$ is a compact connected $m$ dimensional manifold without boundary. Also, let $U, W \subset M$ be two disjoint open neighborhoods which are the domains of two local charts $(W, \varphi),(U, \psi)$ of $M$. Take two gradient MorseSmale vector fields on $M$, each of which possesses a unique hyperbolic repelling equilibrium $q_{i}$ and a unique hyperbolic attracting equilibrium $p_{i}, i=0,1$, and finitely many saddle points $r_{j}^{i}, i=0,1, j=1, \ldots, l$, contained in open domains $V_{j} \subset M \backslash(U \cup W)$.

Assume that the fixed points $p_{0}$ and $q_{1}$ are distinct points contained in $U$ and $p_{1}$ and $q_{0}$ are also distinct points that are contained in $W$. Let $f_{0}$ and $f_{1}$ be their time- 1 maps. Suppose that the mappings $f_{i}, i=0,1$, have no saddle connection. Also, we can choose the coordinate functions $\varphi$ and $\psi$ satisfying the following conditions.
(i) If we take $\widehat{f}_{i}:=\psi \circ f_{i} \circ \psi^{-1}$, then $\widehat{f}_{i}$ are affine maps which are defined by

$$
\begin{gather*}
\widehat{f_{0}}\left(x_{1}, \ldots, x_{m}\right)=\left( \pm r x_{m}+s, r x_{1}, \ldots, r x_{m-1}\right), \\
\widehat{f_{1}}\left(x_{1}, \ldots, x_{m}\right)=\left(-a x_{1}, a x_{2}, \ldots, a x_{m-1},-a x_{m}-2 \frac{s}{r}\right), \tag{9}
\end{gather*}
$$

for constants $0<r<1,0<s<a-1, a>1$ and ar < 1 . We consider a minus sign for even $m$ and a plus sign for odd $m$. By construction,

$$
\begin{align*}
& \widehat{f_{0}} \circ \widehat{f}_{1}\left(x_{1}, \ldots, x_{m}\right)  \tag{10}\\
& \quad=\left( \pm \operatorname{ar} x_{m}-s,-\operatorname{ar} x_{1}, \operatorname{ar} x_{2}, \ldots, \operatorname{ar} x_{m-1}\right)
\end{align*}
$$

is a contracting map.
(ii) If we take $\widetilde{f}_{i}:=\varphi \circ f_{i} \circ \varphi^{-1}, i=0,1$, then ${\widetilde{f_{0}}}_{0}=\widehat{f}_{0}^{-1}$ and $\widetilde{f_{1}}={\widehat{f_{0}}}^{\circ}{\widehat{f_{1}}}^{-1} \circ{\widehat{f_{0}}}^{-1}$. So ${\widetilde{f_{0}}}^{-1}=\widehat{f_{0}}$ and $\left(\widetilde{f_{0}} \circ \widetilde{f_{1}}\right)^{-1}=$ $\widehat{f_{0}} \circ \widehat{f_{1}}$. Moreover, $\widetilde{f_{1}}$ is an affine contracting map.
Note that there is a compact invariant set $\Delta=\Delta_{\mathscr{F}} \subset U$ with nonempty interior which contains the fixed points $p_{0}$ and $q_{1}$, such that the acting of the iterated function system generated by $\left\{f_{0}, f_{0} \circ f_{1}\right\}$ on $\Delta$ is minimal. Moreover, the iterated function system $\mathscr{F}\left(M ; f_{0}, f_{1}\right)$ is $C^{1}$-robustly minimal (see [3] for more detail).

Put $h_{0}:=f_{0}$ and $h_{1}:=f_{0} \circ f_{1}$. Let us define $\mathscr{L}(\Delta)=$ $h_{0}(\Delta) \cup h_{1}(\Delta)$. Suppose that $\Delta_{\text {in }} \subset \Delta \subset \Delta_{\text {out }}$ are two open sets close to $\Delta$ on which $h_{0}$ and $h_{1}$ are contracting. Then

$$
\begin{equation*}
\Delta_{\text {in }} \subset \mathscr{L}\left(\Delta_{\text {in }}\right) \subset \Delta \subset \mathscr{L}\left(\Delta_{\text {out }}\right) \subset \Delta_{\text {out }} \tag{11}
\end{equation*}
$$

and $\mathscr{L}^{i}\left(\Delta_{\text {in }}\right), \mathscr{L}^{i}\left(\Delta_{\text {out }}\right)$ converge to $\Delta$ in the Hausdorff topology, as $i \rightarrow \infty$, provided that the fiber maps $f_{i}$ are sufficiently close to the identity map. This requires that the constants $a$ and $r$ are sufficiently close to 1 .

Moreover, our construction shows that the iterated function system $\mathscr{F}\left(M ; f_{0}^{-1}, f_{1}^{-1}\right)$ is also minimal. Also, there exists a compact invariant set $\Delta^{\prime}=\Delta_{\mathscr{F}}^{\prime} \subset W$ that contains the fixed points $q_{0}$ and $p_{1}$ in its interior such that the iterated function system $\mathscr{F}\left(\Delta^{\prime} ; f_{0}^{-1},\left(f_{0} \circ f_{1}\right)^{-1}\right)$ is minimal. In particular, there exist open sets $\Delta_{\text {in }}^{\prime} \subset \Delta^{\prime} \subset \Delta_{\text {out }}^{\prime}$ satisfying the inclusion relations (11).

In the rest of this section, we fix the mappings $f_{i}, i=0,1$, satisfying all the properties mentioned above and we consider the skew product map

$$
\begin{equation*}
F: \Sigma^{2} \times M \longrightarrow \Sigma^{2} \times M, \quad(\omega, x) \longmapsto\left(\sigma \omega, f_{\omega_{0}}(x)\right) \tag{12}
\end{equation*}
$$

with the fiber maps $f_{i}, i=0,1$.
In [3], the authors proved that $F$ is $C^{1}$-robustly topologically mixing on $\Sigma_{11}^{2} \times \Delta$, where $\Sigma_{11}^{2} \subset \Sigma^{2}$ is the set of all sequences from $\Sigma^{2}$ in which the segment " 11 " is not encountered to the right of any element.

Since $f_{i}, i=0,1$, are Morse-Smale diffeomorphisms with a unique attracting fixed point $p_{i}$ and unique repelling fixed
point $q_{i}$ and they have not any saddle connection, so the stable and unstable sets $W^{s}\left(p_{0}, f_{0}\right)$ and $W^{u}\left(q_{1}, f_{1}\right)$ are open and dense subsets of $M$.

Lemma 4. Consider the iterated function system $\mathscr{F}\left(M ; f_{0}, f_{1}\right)$ as aforementioned. For every nonempty open set $U \subset M$, there exist $k \leq k_{0} \in \mathbb{N}$ and $\rho=\rho(U)>0$ such that, for every ball $B \subset M$ of radius less than $\rho$, there exists a finite word $w=t_{1} \cdots t_{k}$ on the alphabets $\{0,1\}$ and with the length $k \leq k_{0}$ such that $\bar{f}_{k}[w](B) \subset U$.

Proof. Let $U \subset M$ be an open subset. Since the acting of $\mathscr{F}$ on $M$ is minimal, for each $x \in M$ there exists a word $w(x)$ on the alphabets $\{0,1\}$ such that $\bar{f}_{|w(x)|}[w(x)](x) \in U$. By continuity, there is a neighborhood $V_{x}$ of $x$ such that $\bar{f}_{|w(x)|}[w(x)]\left(V_{x}\right) \subset$ $U$.

Since $M$ is compact, we can cover $M$ by finitely many open sets $V_{x_{i}}, i=1, \ldots, n$. We take $k_{0}$ as the maximum of the lengths of the words $w\left(x_{i}\right), i=1, \ldots, n$, and $\rho>0$ the Lebesgue number of this covering. Then every ball $B \subset M$ of radius less than $\rho$ is contained in some $V_{x_{i}}$. So there exists a word $w=t_{1} \cdots t_{k}$ on the alphabets $\{0,1\}$ of the length $k \leq k_{0}$ such that $\bar{f}_{k}[w](B) \subset U$.

Remark 5. Since the iterated function system $\mathscr{F}\left(M ; f_{0}^{-1}, f_{1}^{-1}\right)$ is minimal, we can apply the argument used in the proof of Lemma 4 to prove the following statement: for every nonempty open set $U \subset M$, there exists $l \leq l_{0} \in \mathbb{N}$ and $\varrho=\varrho(U)>0$ such that, for every ball $B \subset M$ of radius less than $\varrho$, there exists a finite word $w=s_{1} \cdots s_{l}$ on the alphabets $\{0,1\}$ of the length $l \leq l_{0}$ such that $f_{s_{l}}^{-1} \circ \cdots \circ f_{s_{1}}^{-1}(B) \subset U$.

In the following, we will use the notation

$$
\begin{equation*}
C_{\bar{\alpha}}=\left\{\omega \in \Sigma^{2} \mid \omega_{j}=\alpha_{j},-n \leq j \leq n-1\right\} \tag{13}
\end{equation*}
$$

where $\bar{\alpha}=\alpha_{-n} \cdots \alpha_{0} \cdots \alpha_{n-1}$ is a segment of the symbols $\{0,1\}$.

The rest of this section is devoted to prove Theorem 1.
Proof. First, we will prove that the statement of Theorem 1 holds for the step skew product map $F$ with generators $f_{0}, f_{1}$ which are introduced in the aforementioned. Note that the open sets $C_{\bar{\alpha}} \times U \subset \Sigma^{2} \times M$, form a base of the topology of the space $\Sigma^{2} \times M$ where $\bar{\alpha}=\alpha_{-n} \cdots \alpha_{0} \cdots \alpha_{n-1}$ is a segment of $\{0,1\}, C_{\bar{\alpha}}$ is the cylinder set corresponding to the segment $\bar{\alpha}$, and $U$ is an open set of $M$.

Suppose that the segment $\bar{\alpha}=\alpha_{-n} \cdots \alpha_{0} \cdots \alpha_{n-1}$ and open subset $U \subset M$ are given. We seek a periodic point $((\bar{\beta}), x) \in$ $C_{\bar{\alpha}} \times U$ of the skew product map $F$ which is attracting along $M$. From now on, we fix the open subset $C_{\bar{\alpha}} \times U \subset \Sigma^{2} \times M$.

Let $U_{0}$ be an open ball which is contained in the basin of the attracting fixed point $p_{0}$ of $f_{0}$ such that $\left\|\left.D f_{0}\right|_{U_{0}}\right\| \leq \lambda<1$, for some $0<\lambda<1$. By Lemma 4 , there exist $\rho_{0}:=\rho_{0}\left(U_{0}\right)$ and $k_{0}:=k_{0}\left(U_{0}\right) \in \mathbb{N}$ such that, for every open neighborhood $V$ of diameter less than $\rho_{0}$, there exists a word $w=w\left(V, U_{0}\right)$ on the alphabets $\{0,1\}$ and with the length at most $k$, such that $\bar{f}_{|w|}[w](V) \subset U_{0}$.

Now the following statements hold.
(a) Consider an open ball $W \subset U$ of radius less than $\rho_{0} / L^{n}$. Take $W_{\alpha^{+}}:=\bar{f}_{n}[\bar{\alpha}](W)$; then $\operatorname{diam}\left(W_{\alpha^{+}}\right)<\rho_{0}$. By Lemma 4, there exists a finite word $w=t_{1} \cdots t_{l_{1}}$ on the alphabets $\{0,1\}$ of the length at most $k_{0}$, such that $\bar{f}_{l_{1}}[w]\left(W_{\alpha^{+}}\right) \subset U_{0}$.
(b) Take $W_{\alpha^{-}}:=\bar{f}_{-n}[\bar{\alpha}](W)$. So there exist $\rho_{2}:=\rho_{2}\left(W_{\alpha^{-}}\right)$ and $k_{2}:=k_{2}\left(W_{\alpha^{-}}\right) \in \mathbb{N}$ satisfying the statement of Lemma 4.

Since $U_{0}$ is contained in the basin of attracting fixed point $p_{0}$ of $f_{0}$, so there exists a positive integer $l_{2}$ such that

$$
\begin{equation*}
\operatorname{diam}\left(f_{0}^{l_{2}}\left(\bar{f}_{l_{1}}[w]\left(W_{\alpha^{+}}\right)\right)\right)<\rho_{2}, \quad L^{k_{1}+k_{2}} \lambda^{l_{2}}<1 \tag{14}
\end{equation*}
$$

By statement (b), there exists a word $w^{\prime}=s_{1} \cdots s_{l_{3}}$ on the alphabets $\{0,1\}$ and with the length $l_{3} \leq k_{2}$ such that $\bar{f}_{l_{3}}\left[w^{\prime}\right]$ $\left(f_{0}^{l_{2}}\left(\bar{f}_{l_{1}}[w]\left(W_{\alpha^{+}}\right)\right)\right) \subset W_{\alpha^{-}}$.

We set $\bar{\beta}=\beta_{-m} \cdots \beta_{-1} \beta_{0} \cdots \beta_{m-1}$, where

$$
\begin{align*}
\beta_{-m} \cdots \beta_{-1} & =\beta_{0} \cdots \beta_{m-1} \\
& =\alpha_{0} \cdots \alpha_{n-1} t_{1} \cdots t_{l_{1}} \frac{0 \cdots 0}{l_{2} \text { times }} s_{1} \cdots s_{l_{3}} \alpha_{-n} \cdots \alpha_{-1} \tag{15}
\end{align*}
$$

and $m=l_{1}+l_{2}+l_{3}+2 n$, which implies that $\bar{f}_{2 m}[\bar{\beta}](W) \subset W$. Moreover, the choice of $l_{2}$ shows that $\left\|\left.D \bar{f}_{2 m}[\bar{\beta}]\right|_{W}\right\|<1$.

According to these facts, there exists an attracting fixed point $x$ for the mapping $\bar{f}_{\underline{2} m}[\bar{\beta}]$ which is contained in $W \subset U$. So the periodic point $((\bar{\beta}), x)$ which is attracting along the fiber lies in $C_{\bar{\alpha}} \times U$.

Density of periodic orbits which are repelling along $M$ can be established similarly.

Indeed, by applying Remark 5 and since the mapping $f_{1}^{-1}$ is contracting on $\Delta^{\prime}$, there exist an open set $W \subset U$ and a finite word $w^{\prime \prime}=r_{1} \cdots r_{k}$ on the alphabets $\{0,1\}$, such that

$$
\begin{gather*}
f_{r_{k}}^{-1} \circ \cdots \circ f_{r_{1}}^{-1} \circ \bar{f}_{-n}[\bar{\alpha}](W) \subset \bar{f}_{n}[\bar{\alpha}](W), \\
\left\|\left.\left(\bar{f}_{n}[\bar{\alpha}]\right)^{-1} \circ f_{r_{k}}^{-1} \circ \cdots \circ f_{r_{1}}^{-1} \circ \bar{f}_{-n}[\bar{\alpha}]\right|_{W}\right\|<1 . \tag{16}
\end{gather*}
$$

So there exists an attracting fixed point $y$ for the map

$$
\begin{align*}
& \left(f_{\alpha_{-1}} \circ \cdots \circ f_{\alpha_{-n}} \circ \bar{f}_{k}\left[w^{\prime \prime}\right] \circ \bar{f}_{n}[\bar{\alpha}]\right)^{-1} \\
& \quad=\left(\bar{f}_{n}[\bar{\alpha}]\right)^{-1} \circ f_{r_{k}}^{-1} \circ \cdots \circ f_{r_{1}}^{-1} \circ \bar{f}_{-n}[\bar{\alpha}] \tag{17}
\end{align*}
$$

which is contained in $W$.
Now, we take $\bar{\gamma}=\gamma_{-l} \cdots \gamma_{-1} \gamma_{0} \cdots \gamma_{l-1}$, where

$$
\begin{equation*}
\gamma_{-l} \cdots \gamma_{-1}=\gamma_{0} \cdots \gamma_{l-1}=\alpha_{0} \cdots \alpha_{n-1} r_{1} \cdots r_{k} \alpha_{-n} \cdots \alpha_{-1} \tag{18}
\end{equation*}
$$

and $l=k+2 n$. Then $((\bar{\gamma}), y)$ is a periodic point for the skew product map $F$ which is repelling along $M$ and lies in $C_{\bar{\alpha}} \times U$.

Now, let us prove that the statement holds for small perturbations of $F$, that is, step skew product maps generated by small perturbations of $f_{0}$ and $f_{1}$. Choose $g_{0} \in U_{0}$ and
$g_{1} \in U_{1}$, sufficiently close to $f_{0}$ and $f_{1}$ and consider the step skew product map $G$ given by (1) and with the fiber maps $g_{i}, i=0,1$. Therefore, $g_{i}, i=0,1$, possesses a unique hyperbolic repelling fixed point close to $q_{i}, i=0,1$, a unique hyperbolic attracting fixed point close to $p_{i}, i=$ 0,1 , and finitely many saddle points which are close to $r_{j}^{i}$, $i=0,1, j=1, \ldots, l$. Moreover, the iterated function system $\mathscr{G}\left(M ; g_{0}, g_{1}\right)$ is minimal and admits an invariant set $\Delta=$ $\Delta_{\mathscr{G}}$ with nonempty interior which contains the attracting fixed point of $g_{0}$ and the repelling fixed of $g_{1}$, such that $\mathscr{G}\left(\Delta ; g_{0}, g_{0} \circ g_{1}\right)$ is minimal. Moreover, the iterated function system $\mathscr{G}\left(M ; g_{0}^{-1}, g_{1}^{-1}\right)$ is also minimal. So similar reasoning implies the existence of an attracting (repelling) periodic orbit for the map $G$ which is contained in $C_{\bar{\alpha}} \times U$. This terminates the proof of Theorem 1.

## 3. Soft Skew Products

In this section, we prove Theorem 2. In fact, we describe the properties of soft skew product maps which have an $m$ dimensional closed manifold $M$ as a fiber. To translate the properties of step skew product maps to the case of soft skew product maps, we need a Hölder property.

In the following, we provide an open set in the space of soft systems (3) with the Hölder property that has the same properties of step systems.

To be more precise, let us describe them in details.
First, note that if $G$ is a soft skew product of the form (3), then it is obvious that, for $n \in \mathbb{N}$,

$$
\begin{align*}
G^{n}(\omega, x) & =\left(\sigma^{n} \omega, \bar{g}_{n}[w](x)\right) \\
G^{-n}(\omega, x) & =\left(\sigma^{-n} \omega, \bar{g}_{-n}[w](x)\right) \tag{19}
\end{align*}
$$

where

$$
\begin{gather*}
\bar{g}_{n}[\omega]=g_{\sigma^{n-1} \omega} \circ \cdots \circ g_{\sigma \omega} \circ g_{\omega} \\
\bar{g}_{-n}[\omega]=g_{\sigma^{-n} \omega}^{-1} \circ \cdots \circ g_{\sigma^{-1} \omega}^{-1}, \quad \bar{g}_{0}[\omega]=\mathrm{id} \tag{20}
\end{gather*}
$$

Let $f_{0}$ and $f_{1}$ be two diffeomorphisms on $M$ generating a robustly minimal iterated function system as in the previous section. Write $h_{0}:=f_{0}, h_{1}:=f_{0} \circ f_{1}$ and let $\mathscr{F}$ be the iterated function system generated by $h_{0}$ and $h_{1}$. Recall that the iterated function system $\mathscr{F}$ acts minimally on a compact invariant set $\Delta$. Also, there are open sets $\Delta_{\text {in }} \subset \Delta \subset \Delta_{\text {out }}$ on which

$$
\begin{equation*}
\Delta_{\text {in }} \subset \mathscr{F}\left(\Delta_{\text {in }}\right) \subset \Delta \subset \mathscr{F}\left(\Delta_{\text {out }}\right) \subset \Delta_{\text {out }}, \tag{21}
\end{equation*}
$$

and $h_{0}$ and $h_{1}$ are contractions on $\Delta_{\text {out }}$.
Moreover, our construction in Section 2 shows that the iterated function system $\mathscr{F}\left(M ; f_{0}^{-1}, f_{1}^{-1}\right)$ is also minimal. Also, there exists a compact invariant set $\Delta^{\prime}$ which contains the attracting fixed point of $f_{1}$ and repelling fixed point of $f_{0}$ in its interior such that the iterated function system $\mathscr{F}\left(\Delta^{\prime} ; f_{0}^{-1},\left(f_{0} \circ f_{1}\right)^{-1}\right)$ is minimal. In particular, there exist open sets $\Delta_{\text {in }}^{\prime} \subset \Delta^{\prime} \subset \Delta_{\text {out }}^{\prime}$ satisfying the inclusion relations (21) corresponding to $\mathscr{F}\left(\Delta^{\prime} ; f_{0}^{-1},\left(f_{0} \circ f_{1}\right)^{-1}\right)$.

Let $F$ on $\Sigma^{2} \times M$ be defined by

$$
\begin{equation*}
F(\omega, x)=\left(\sigma(\omega), h_{\omega_{0}}(x)\right) \tag{22}
\end{equation*}
$$

where $(\sigma(\omega))_{k}=\omega_{k+1}$ is the left shift operator. Suppose that $G$ is a soft skew product map of the form (3) such that $g_{\omega}$ depends continuously on $\omega$ and is uniformly close to $h_{\omega_{0}}$, by a uniform bound $\delta>0$. Then the inclusions (21) get replaced by

$$
\begin{equation*}
\Sigma^{2} \times \Delta_{\text {in }} \subset G\left(\Sigma^{2} \times \Delta_{\text {in }}\right), \quad\left(\Sigma^{2} \times \Delta_{\text {out }}\right) \subset \Sigma^{2} \times \Delta_{\text {out }}, \tag{23}
\end{equation*}
$$

for sufficiently small $\delta$. Moreover, the choice of $\Delta_{\text {in }}$ can be independent of skew product map $G$. This means that if $G$ is any soft skew product of the form (3) with the fiber maps $g_{\omega}$, with $d_{C^{1}}\left(g_{\omega}, h_{\omega_{0}}\right)<\delta$, for any $\omega \in \Sigma^{2}$, then the inclusions (23) hold for $G$. By the argument used in the proof of [3, Proposition 5.1], the next lemma follows; see also [4, Proposition 5.1].

Lemma 6. Let $F$ be the step skew product map as in the aforementioned and by fiber maps $h_{i}, i=0,1$. Then any soft skew product map $G$ of the form (3) which is sufficiently close to $F$ possesses a maximal invariant set $\Lambda_{G} \subset \Sigma^{2} \times \Delta_{\text {out }}$ on which the acting $G$ is topologically mixing. Moreover, there is an open set $\Delta_{\text {in }}$ such that for any soft system $G, \Delta_{\text {in }} \subset \pi\left(\Lambda_{G}\right)$, where $\pi: \Sigma^{2} \times M \rightarrow M$ is the natural projection.

Since the diffeomorphisms $f_{i}, i=0,1$, are Morse-Smale and the set of all Morse-Smale diffeomorphisms is open subset of $\operatorname{Diff}^{2}(M)$, so we can choose two neighborhoods $U_{0}\left(f_{0}\right), U_{1}\left(f_{1}\right) \subset \operatorname{Diff}^{2}(M)$ sufficiently small such that the following statements hold.

If $G$ is a soft skew product of the form (3) with fiber maps $g_{\omega} \in U_{\omega_{0}}\left(f_{\omega_{0}}\right), \omega \in \Sigma^{2}$, then
(i) the mapping $g_{\omega}$ has one hyperbolic attracting fixed point $p(\omega)$, one hyperbolic repelling fixed point $q(\omega)$, and finitely many saddle points $r_{i}(\omega), i=1, \ldots, l$;
(ii) all attracting fixed points of the mappings $g_{\omega}$, with $\omega_{0}=0$, and all repelling fixed points of the mappings $g_{\omega}$, with $\omega_{0}=1$, lie strictly inside $\Delta_{\text {in }}$;
(iii) all attracting fixed points of the mappings $g_{\omega}$, with $\omega_{0}=1$, and all repelling fixed points of the mappings $g_{\omega}$, with $\omega_{0}=0$, lie strictly inside $\Delta_{\text {in }}^{\prime}$;
(iv) stable sets $W^{s}\left(p_{\omega}, g_{\omega}\right)$ are open and dense subsets of $M$, for any $\omega \in \Sigma^{2}$ with $\omega_{0}=0$;
(v) unstable sets $W^{u}\left(q_{\omega}, g_{\omega}\right)$ are open and dense subsets of $M$, for any $\omega \in \Sigma^{2}$ with $\omega_{0}=1$.

We say that the soft skew product map $G$ is controllable if its fiber maps $g_{\omega}, \omega \in \Sigma^{2}$, satisfying the assumptions of Theorem 2 and all of the properties mentioned above.

In the following, we establish the density of periodic points of a controllable soft skew product map $G$ which are attracting along the fiber $M$.

Indeed, we will find a periodic point in any open set of the form $C_{\bar{\alpha}} \times U \subset \Sigma^{2} \times M$, where $\bar{\alpha}=\alpha_{-n} \cdots \alpha_{0} \cdots \alpha_{n-1}$ is a finite segment of the alphabets $\{0,1\}, C_{\bar{\alpha}}$ is the cylinder set corresponding to it, and $U$ is an open subset of $M$.

First, we need the following lemma which controls the error in the coordinate along the fiber. It is obtained by an argument used in [1, Lemma 3.1].

Lemma 7. Let $G$ be a controllable soft skew product map. Then there exists $K>0$, with $K=K(L, C, \alpha)$ and being independent of $\delta>0$, such that, for any $m \in \mathbb{N}$, the inequality $d_{\Sigma^{2}}\left(\omega, \omega^{\prime}\right) \leq$ $2^{-m}$ implies

$$
\begin{equation*}
d_{C^{0}}\left(\bar{g}_{ \pm m}[\omega], \bar{g}_{ \pm m}\left[\omega^{\prime}\right]\right) \leq \gamma:=K \delta^{\beta} \tag{24}
\end{equation*}
$$

where $\beta=1-\ln L / \ln 2^{\alpha}$.
According to Lemma 7, for each controllable soft skew product $G$ with the fiber maps $g_{\omega}$,

$$
\begin{equation*}
\operatorname{diam}\left\{\bar{g}_{ \pm m}[\omega](x) \mid \omega=\left\{\cdots w^{\star} \cdots\right\}\right\} \leq \gamma \tag{25}
\end{equation*}
$$

for any $x \in M$, any $m \in \mathbb{N}$, and any finite word $w^{\star}=$ $w_{-m} \cdots w_{-1} \cdot w_{0} \cdots w_{m}$.

Let us note that if $\delta>0$ is sufficiently small, then $\gamma>0$ is also small enough. By Lemma 6, the controllable soft skew product $G$ is topologically mixing on $\Sigma_{11}^{2} \times \Delta$, where $\Sigma_{11}^{2} \subset \Sigma^{2}$ is the set of all sequences from $\Sigma^{2}$ in which the segment " 11 " is not encountered to the right of any element.

We now begin the proof of Theorem 2.
Proof. Suppose that the segment $\bar{\alpha}=\alpha_{-n} \cdots \alpha_{0} \cdots \alpha_{n-1}$ and open neighborhood $U \subset M$ are given. Our aim is to find a periodic point in $C_{\bar{\alpha}} \times U$, where $C_{\bar{\alpha}}$ is the cylinder set corresponding to $\bar{\alpha}$.

We recall that the stable sets $W^{s}\left(p_{\omega}, g_{\omega}\right)$ are open and dense subsets of manifold $M$, for any $\omega \in \Sigma^{2}$ with $\omega_{0}=0$, so

$$
\begin{equation*}
\bar{g}_{m}[\omega](U) \cap W^{s}\left(p_{\sigma^{m} \omega}, g_{\sigma^{m} \omega}\right) \neq \emptyset \tag{26}
\end{equation*}
$$

for any $m \in \mathbb{N}$. This implies that there exists a neighborhood $U_{\omega}^{1} \subset U$, such that $\bar{g}_{n}[\omega]\left(U_{\omega}^{1}\right) \subset W^{s}\left(p_{\sigma^{n} \omega}, g_{\sigma^{n} \omega}\right)$, for any sequence $\omega=\left\{\cdots \mid \alpha_{0} \cdots \alpha_{n-1} 0 \cdots\right\}$.

Similarly, $\bar{g}_{n+1}[\omega]\left(U_{\omega}^{1}\right) \cap W^{s}\left(p_{\sigma^{n+1} \omega}, g_{\sigma^{n+1} \omega}\right) \neq \emptyset$, which implies that there is a neighborhood $U_{\omega}^{2} \subset U_{\omega}^{1}$, such that $\bar{g}_{n+1}[\omega]\left(U_{\omega}^{2}\right)$ is contained in $W^{s}\left(p_{\sigma^{n+1} \omega}, g_{\sigma^{n+1} \omega}\right)$, for any sequence $\omega=\left\{\cdots \mid \alpha_{0} \cdots \alpha_{n-1} 00 \cdots\right\}$.

By continuing the above procedure, we obtain neighborhoods

$$
\begin{equation*}
U_{\omega}^{k} \subset U_{\omega}^{k-1} \subset \cdots U_{\omega}^{1} \subset U \tag{27}
\end{equation*}
$$

such that

$$
\begin{equation*}
\bar{g}_{n+k-1}[\omega]\left(U_{\omega}^{k}\right) \subset W^{s}\left(p_{\sigma^{n+k-1} \omega}, g_{\sigma^{n+k-1} \omega}\right) \tag{28}
\end{equation*}
$$

for any sequence

$$
\begin{equation*}
\omega=\{\cdots \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k} \cdots\} . \tag{29}
\end{equation*}
$$

Since attracting fixed points of mappings $g_{\omega}$, for any $\omega \in$ $\Sigma^{2}$, are contained in $\Delta_{\text {in }}$, so by increasing $k$, the subset $\bar{g}_{n+k}[\omega]\left(U_{\omega}^{k}\right)$ intersects with $\Delta_{\text {in }}$. Therefore, there exists a positive integer $k_{0}$ such that $\bar{g}_{n+k_{0}}[\omega]\left(U_{\omega}^{k_{0}}\right) \cap \Delta_{\text {in }} \neq \emptyset$. Also, there is an open set $\widetilde{U}_{\omega} \subset U_{\omega}^{k_{0}}$ such that $\bar{g}_{n+k_{0}}[\omega]\left(\widetilde{U}_{\omega}\right) \subset \Delta_{\text {in }}$, for any sequence $\omega=\{\cdots \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} \cdots\}$.

By shrinking $\bar{g}_{n+k_{0}}[\omega]\left(\widetilde{U}_{\omega}\right)$, we can control the error in the coordinate along the fiber. To do this, we note that the map $g_{\omega}$, with $\omega_{0}=0$, and the map $\bar{g}_{2}[\omega]$, with $\omega_{0}=$ $1, \omega_{1}=0$, are contracting on $\Delta_{\text {in }}$, so there exists a finite word $T=t_{1} \cdots t_{l_{1}}$ such that $\bar{g}_{n+k_{0}+l_{1}}[\omega]\left(\widetilde{U}_{\omega}\right)$ is contained in an open ball $U_{\omega}^{+}$of $\Delta_{\text {in }}$ with diameter $2 \gamma$, for any $\omega=\{\cdots \mid$ $\alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\}$.

Analogously, since the unstable subsets $W^{u}\left(p_{\omega}, g_{\omega}\right)$ are open and dense subsets of manifold $M$, for any $\omega \in \Sigma^{2}$ with $\omega_{0}=1$, so

$$
\begin{equation*}
\bar{g}_{-m}[\omega](U) \cap W^{s}\left(q_{\sigma^{-m-1} \omega}, g_{\sigma^{-m-1} \omega}^{-1}\right) \neq \emptyset \tag{30}
\end{equation*}
$$

for any $m \in \mathbb{N}$ and $\omega \in \Sigma^{2}$ with $\omega_{-m-1}=1$. This implies that there exists a neighborhood $W_{\omega}^{1} \subset \widetilde{U}_{\omega}$, such that $\bar{g}_{-n}[\omega]\left(W_{\omega}^{1}\right) \subset W^{s}\left(q_{\sigma^{-n-1} \omega}, g_{\sigma^{-n-1} \omega}^{-1}\right)$, for any sequence $\omega=\{\cdots$ $1 \alpha_{-n} \cdots \alpha_{-1} \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\}$.

Similarly, $\bar{g}_{-n-1}[\omega]\left(W_{\omega}^{1}\right) \cap W^{s}\left(q_{\sigma^{-n-2} \omega}, g_{\sigma^{-n-2} \omega}^{-1}\right) \neq \emptyset$, so there exists a neighborhood $W_{\omega}^{2} \subset W_{\omega}^{1}$, such that $\bar{g}_{-n-1}[\omega]$ $\left(W_{\omega}^{2}\right) \subset W^{s}\left(q_{\sigma^{-n-2} \omega}, g_{\sigma^{-n-2} \omega}^{-1}\right)$, for any $\omega=\left\{\cdots 11 \alpha_{-n} \cdots \alpha_{-1} \mid\right.$ $\alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\}$.

By induction, we obtain neighborhoods

$$
\begin{equation*}
W_{\omega}^{m} \subset W_{\omega}^{m-1} \subset \cdots W_{\omega}^{1} \subset \widetilde{U}_{\omega} \tag{31}
\end{equation*}
$$

such that

$$
\begin{equation*}
\bar{g}_{-n-m+1}[\omega]\left(W_{\omega}^{m}\right) \subset W^{s}\left(q_{\sigma^{-n-m} \omega}, g_{\sigma^{-n-m} \omega}^{-1}\right) \tag{32}
\end{equation*}
$$

for any sequence of the form

$$
\begin{equation*}
\omega=\{\cdots \underbrace{1 \cdots 1}_{m} \alpha_{-n} \cdots \alpha_{-1} \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\} . \tag{33}
\end{equation*}
$$

Since repelling fixed points of mappings $g_{\omega}$, for any $\omega \in \Sigma^{2}$ with $\omega_{0}=1$, are contained in $\Delta_{\text {in }}$, so by increasing $m, \bar{g}_{-n-m}$ $[\omega]\left(W_{\omega}^{m}\right)$ intersects with $\Delta_{\text {in }}$; therefore, there exist a positive integer $m_{0}$ such that $\bar{g}_{-n-m_{0}}[\omega]\left(W_{\omega}^{m_{0}}\right) \cap \Delta_{\text {in }} \neq \emptyset$ and an open set $\widetilde{W}_{\omega} \subset W_{\omega}^{m_{0}}$ such that $\bar{g}_{-n-m_{0}}[\omega]\left(\widetilde{W}_{\omega}\right) \subset \Delta_{\text {in }}$, for any sequence

$$
\begin{equation*}
\omega=\{\left.\cdots \frac{1 \cdots 1}{m_{0}} \alpha_{-n} \cdots \alpha_{-1} \right\rvert\, \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\} . \tag{34}
\end{equation*}
$$

The construction shows that the mapping $\bar{g}_{-1}[\omega]$, with $\omega_{-1}=0$, and the mapping $\bar{g}_{-2}[\omega]$, with $\omega_{-1}=0$ and $\omega_{-2}=1$,
are expanding on $\Delta_{\text {in }} \subset \Delta$, so there exists a finite word $S=s_{l_{0}} \cdots s_{1}$ such that, for any sequence $\omega$ of the form

$$
\begin{equation*}
\omega=\{\cdots S_{m_{0}}^{1 \cdots 1} \alpha_{-n} \cdots \alpha_{-1} \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\}, \tag{35}
\end{equation*}
$$

$\bar{g}_{-\left(n+m_{0}+l_{0}\right)}[\omega]\left(\widetilde{W}_{\omega}\right)$ contains an open ball $W_{\omega}^{-}$of diameter $6 \gamma$. Note that by shrinking the $C^{2}$-neighborhoods $U_{0}\left(g_{0}\right), U_{1}\left(g_{1}\right) \subset \operatorname{Diff}^{2}(M)$, if it is necessary, we may assume that $6 \gamma<\operatorname{diam}\left(\Delta_{\text {in }}\right)$.

Since $\widetilde{W}_{\omega} \subset \widetilde{U}_{\omega}$, the subset $\bar{g}_{n+k_{0}+l_{1}}[\omega]\left(\widetilde{W}_{\omega}\right)$ is contained in an open ball $U_{\omega}^{+}$of $\Delta_{\text {in }}$ with diameter $2 \gamma$, for any sequence of the form

$$
\begin{equation*}
\omega=\{\cdots S \underbrace{1 \cdots 1}_{m_{0}} \alpha_{-n} \cdots \alpha_{-1} \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T \cdots\} . \tag{36}
\end{equation*}
$$

We recall that the acting of $G$ is topologically mixing on $\Sigma_{11}^{2} \times \Delta$, so there exists a finite word $R_{\omega}=r_{1} \cdots r_{k_{\omega}} \in \Sigma_{11}^{2}$, $k_{\omega}>k_{0}$, such that, for any sequence $\omega=\left\{\cdots \mid{ }^{\omega} R_{\omega} \cdots\right\}$, $B_{\gamma}\left(\bar{g}_{k_{\omega}}[\omega]\left(U_{\omega}^{+}\right)\right) \subset W_{\omega}^{-}$.

Take the segment

$$
\begin{equation*}
w:=S \underbrace{1 \cdots 1}_{m_{0}} \alpha_{-n} \cdots \alpha_{-1} \mid \alpha_{0} \cdots \alpha_{n-1} \underbrace{0 \cdots 0}_{k_{0}} T R \tag{37}
\end{equation*}
$$

and the periodic sequence $\widetilde{\beta}:=(w)$.
Now the constructions show that $\bar{g}_{n+k_{0}+l_{1}}[\widetilde{\beta}]\left(\widetilde{W}_{\widetilde{\beta}}\right)$ is contained in an open ball $U_{\tilde{\beta}}^{+}$in $\Delta_{\text {in }}$ of diam $2 \gamma$, and $\bar{g}_{-\left(n+m_{0}+l_{0}\right)}[\widetilde{\beta}]\left(\widetilde{W}_{\tilde{\beta}}\right)$ contains an open ball $W_{\tilde{\beta}}^{-}$of diam $6 \gamma$. So

$$
\begin{align*}
& \left(\bar{g}_{-\left(n+m_{0}+l_{0}\right)}[\widetilde{\beta}]\right)^{-1}\left(W_{\tilde{\beta}}^{-}\right)  \tag{38}\\
& \quad=\bar{g}_{n+m_{0}+l_{0}}\left[\sigma^{-\left(n+m_{0}+l_{0}\right)} \widetilde{\beta}\right]\left(W_{\tilde{\beta}}^{-}\right) \subset \widetilde{W}_{\widetilde{\beta}} .
\end{align*}
$$

Let $m=2 n+l_{0}+l_{1}+m_{0}+K_{0}+k$. According to Lemma 7 and the fact $\bar{g}_{k_{\tilde{\beta}}}\left[\sigma^{n+k+l_{1}} \widetilde{\beta}\right]\left(U_{\tilde{\beta}}^{+}\right) \subset W_{\tilde{\beta}}^{-}$, we conclude that

$$
\begin{equation*}
\bar{g}_{m}[\widetilde{\beta}]\left(\widetilde{W}_{\widetilde{\beta}}\right) \subset \widetilde{W}_{\widetilde{\beta}} . \tag{39}
\end{equation*}
$$

Note that the acting of $g_{\omega}$, with $\omega_{0}=0$, and $g_{\omega^{\prime}}$, with $\omega_{0}^{\prime}=1$ and $\omega_{1}^{\prime}=0$, are contracting on $\Delta_{\text {in }}$, so we can choose $k_{\widetilde{\beta}}$ sufficiently large such that $\left\|D \bar{g}_{m}[\widetilde{\beta}]\right\|<1$ on $\widetilde{W}_{\widetilde{\beta}}$.

Hence, $\bar{g}_{m}[\widetilde{\beta}]$ has an attracting fixed point $\widetilde{y} \in \widetilde{W}_{\widetilde{\beta}}$. So $\widetilde{Y}=$ $((\widetilde{\beta}), \tilde{y})$ is a periodic point in $C_{\bar{\alpha}} \times U$ which is attracting along the fiber. By a similar argument, we conclude the existence of a periodic point in $C_{\bar{\alpha}} \times U$ which is repelling along the fiber. This completes the proof of Theorem 2.

## 4. Perturbations

Let $n$ and $m$ be positive integers with $n \geq m+3, n \geq 5$, and $m \geq 1$. Suppose that $N$ is an $n$-dimensional closed manifold.

In this section, we will construct an open set $\mathscr{U}$ of $\operatorname{Diff}^{2}(N)$ that satisfies the following property: each diffeomorphism of $\mathscr{U}$ possesses a partially hyperbolic locally maximal invariant set with a dense subset of periodic points with different indices.

In fact, we will find diffeomorphisms such that the restriction of them to their locally maximal invariant sets is conjugated to step random dynamical systems of the form (1).

As we have mentioned before, many properties observed for these products appear to persist as properties of diffeomorphisms [1,2].

In the following, first we need to introduce skew products over the horseshoe which can be considered as smooth realizations of skew products over the Bernoulli shift of the forms (1) and (3).

Indeed, suppose that $h: S^{2} \rightarrow S^{2}$ is a diffeomorphism with a horseshoe type hyperbolic set $\Lambda$, which has a Markov partition with two rectangles $D_{0}, D_{1}$ such that $D_{0} \cap D_{1}=$ $\emptyset$, with the rate of contraction $k \in(0,1)$ which is small enough (see [1, Theorem 2]). Put $D:=D_{0} \cup D_{1}$ and $h(D):=$ $D^{\prime}$. It is well known that the hyperbolic invariant set $\Lambda$ is homeomorphic to $\Sigma^{2}$ with restriction of $h$ to $\Lambda$ being conjugate to the Bernoulli shift $\sigma$ on $\Sigma^{2}$.

Now we define a skew product over the horseshoe map $h: \Lambda \rightarrow \Lambda$ with the fiber map $M$ as follows:

$$
\begin{gather*}
\mathscr{F}: D \times M \longrightarrow D^{\prime} \times M, \\
\left.\mathscr{F}\right|_{D_{i} \times M}=h \times f_{i}, \quad i=0,1, \tag{40}
\end{gather*}
$$

where the diffeomorphism $f_{i}: M \rightarrow M, i=0,1$, are the generators of a skew products $F$ of the form (1). The skew product $\mathscr{F}$ is called a smooth realization of the skew product $F$. It is easy to see that $\Lambda \times M$ is partially hyperbolic for $\mathscr{F}$ and $\left.\mathscr{F}\right|_{\Lambda \times M}$ is conjugate to step skew product $F$. This fact implies that the properties found during the investigation of a semigroup generated by the diffeomorphisms $f_{i}: M \rightarrow M$ are realized by smooth mapping $\mathscr{F}$.

Suppose that $\mathscr{G}$ is a $C^{2}$ skew product which is $C^{1}$-close to $\mathscr{F}$. Then $\mathscr{G}$ has an invariant set $\mathscr{Y}_{\mathscr{G}}$ homeomorphic to $\Sigma^{2} \times M$ by a homeomorphism $K$ (see [2]). Let $\pi: \Sigma^{2} \times$ $M \rightarrow M$ be the projection to the fiber along the base. The homeomorphism $K: \Sigma^{2} \times M \rightarrow \mathscr{Y}_{\mathscr{G}}, \mathscr{Y}_{\mathscr{G}} \subset D \times M$, can be taken so that the coordinate $x$ is preserved, and hence the restriction of $K$ to a single fiber is a $C^{2}$-diffeomorphism. One can consider the induced mapping

$$
\begin{equation*}
G=K^{-1} \circ \mathscr{G} \circ K: \Sigma^{2} \times M \longrightarrow \Sigma^{2} \times M \tag{41}
\end{equation*}
$$

Let us denote the mapping $\pi \circ K^{-1} \circ \mathscr{G} \circ K(\omega, \cdot): M \rightarrow M$ by $g_{\omega}$ which depends on $\omega$. Then $g_{\omega}$ is $C^{2}$ and the mapping $G$ has the following form:

$$
\begin{equation*}
G: \Sigma^{2} \times M \longrightarrow \Sigma^{2} \times M, \quad(\omega, x) \longrightarrow\left(\sigma \omega, g_{\omega}(x)\right) \tag{42}
\end{equation*}
$$

which is a soft skew product (see [2] for more detail). We say that $G$ is a soft skew product corresponding to $\mathscr{G}$ or $\mathscr{G}$ is a $k$ realization of $G$. Moreover, the bundle map $g_{\omega}$ is $C^{1}$-close to $f_{\omega_{0}}$ for each $\omega \in \Sigma^{2}$.

Here, we take $M=S^{m}$, the $m$-dimensional sphere. Let $f_{0}$ and $f_{1}$ be two diffeomorphisms on $S^{m}$ generating a robustly minimal iterated function system as in Sections 2 and 3. Also, let $F$ be the step skew product map of the form (1) with the fiber maps $f_{0}$ and $f_{1}$, and let $\mathscr{F}$ be its smooth realization. Let us take neighborhoods $U_{0}, U_{1}$ as in Theorem 1 .

Now, let $\mathscr{G}$ be $C^{1}$-close to $\mathscr{F}$. Then $\mathscr{G}$ is conjugate to a controllable soft skew product map $G$, with fiber maps $g_{\omega}$ which is $C^{1}$-close to $f_{\omega_{0}}$; see Section 3 for more detail.

Let $\mathscr{H}$ be a $C^{2}$ diffeomorphism which is $C^{1}$-close to $\mathscr{G}$. Then, $\mathscr{H}$ has an invariant set $\mathscr{Y}_{\mathscr{H}}$ homeomorphic to $\Sigma^{2} \times S^{m}$ such that the projection $\left(\mathscr{Y}_{\mathscr{H}}, \mathscr{H}\right) \mapsto\left(\Sigma^{2}, \sigma\right)$ is semiconjugacy and so the dynamics of $\mathscr{H}$ restricted to $\mathscr{Y}_{\mathscr{G}}$ resembles the dynamics of $\left.\mathscr{F}\right|_{\Lambda \times S^{m}}$. Also, $\mathscr{H}$ restricted to $\mathscr{Y}_{\mathscr{H}}$ is conjugate to skew product $H$ on $\Sigma^{2} \times S^{m}$ (see [2]). In particular, the fiber maps $h_{\omega}$ are $C^{1}$-close to $g_{\omega}$ and therefore it is $C^{1}$-close to $f_{\omega_{0}}$, for each $\omega \in \Sigma^{2}$.

Now, we can apply Theorem 2 to conclude that the periodic orbits of the skew product $H$ which are attracting (repelling) along $S^{m}$ are dense in $\Sigma^{2} \times S^{m}$. Therefore, $\mathscr{H}$ restricted to $\mathscr{Y}_{\mathscr{H}}$ has a dense subset of periodic orbits of indices (dimension of their stable manifolds) $l_{1}=1$ and $l_{2}=m+1$.

Finally, one can see that $\mathscr{H}$ restricted to $\mathscr{Y}_{\mathscr{H}}$ can be extended to a diffeomorphism on the closed manifold $N$.

Indeed, one can embed the $m$-sphere $S^{m}$ in $\mathbb{R}^{m+1}$ and a two-dimensional rectangle $B$ in $\mathbb{R}^{n-m-1}$, where $D \subset B, D=$ $D_{0} \cup D_{1}$. So $B \times S^{m}$ can be embedded in the closed manifold $N$, by a local chart of $N$ (see [2] for more detail). This completes the proof of Theorem 3.

## Acknowledgment

The authors are very grateful to the referee for fruitful comments and valuable suggestions.
