

Front evolution of the Fredrickson-Andersen one spin facilitated model*

Oriane Blondel[†] Aurelia Deshayes[‡] Cristina Toninelli[§]

Abstract

The Fredrickson-Andersen one spin facilitated model (FA-1f) on \mathbb{Z} belongs to the class of kinetically constrained spin models (KCM). Each site refreshes with rate one its occupation variable to empty (respectively occupied) with probability q (respectively $p = 1 - q$), provided at least one nearest neighbor is empty. Here, we study the non equilibrium dynamics of FA-1f started from a configuration entirely occupied on the left half-line and focus on the evolution of the front, namely the position of the leftmost zero. We prove, for q larger than a threshold $\bar{q} < 1$, a law of large numbers and a central limit theorem for the front, as well as the convergence to an invariant measure of the law of the process seen from the front.

Keywords: kinetically constrained models; invariant measure; coupling; contact process.

1 Introduction

Fredrickson-Andersen one spin facilitated model (FA-1f) belongs to the class of kinetically constrained spin models (KCM). KCM are interacting particle systems on \mathbb{Z}^d which have been introduced in physics literature in the '80s (see [RS03] for a review) to model the liquid glass transition, a major open problem in condensed matter physics. A configuration of a KCM is given by assigning to each vertex $x \in \mathbb{Z}^d$ an occupation variable $\sigma(x) \in \{0, 1\}$, which corresponds to an empty or occupied site, respectively. The evolution is given by a Markovian stochastic dynamics of Glauber type. With rate one,

each vertex updates its occupation variable to occupied or to empty with probability $p \in [0, 1]$ and $q = 1 - p$, respectively, if the configuration satisfies a certain local constraint. For the FA-1f model the constraint requires at least one empty nearest neighbor. Since the constraint to update the configuration at x does not depend on $\sigma(x)$, the dynamics satisfies detailed balance w.r.t. Bernoulli product measure at density p . A key issue is to analyze the large time evolution when we start from a distribution different from the equilibrium Bernoulli measure. Note that, due to the presence of the constraints, FA-1f dynamics is not attractive, so powerful tools like monotone coupling and censoring inequalities cannot be applied. Furthermore, convergence to equilibrium is not uniform on the initial condition since completely occupied configurations are blocked under the dynamics. Therefore the study of the large time dynamics is particularly challenging. In [BCM+13] a convergence to equilibrium was proven when the starting distribution is such that the mean distance between nearest empty sites is uniformly bounded and the equilibrium vacancy density q is larger than a threshold $1/2$. In [MV18] the result was extended to initial configurations with at least one zero, provided q is sufficiently near to one.

Here, we consider FA-1f on \mathbb{Z} starting from a configuration which has a zero at the origin and is completely occupied in the left half line and we study the evolution of the front, namely the position of the leftmost zero. A law of large numbers and a central limit theorem (Theorem 2.3) for the front, as well as the convergence to an invariant measure of the law of the process seen from the front (Theorem 2.1) are proven. Our results hold for q sufficiently large, more precisely for $q > \bar{q}$ where \bar{q} is related to the critical parameter in the threshold contact process. We stress that, even though we are in one dimension, proving the ballistic motion of the front is non trivial. Indeed, due to the non attractiveness of the dynamics, the classic tool of sub-additivity [Dur80] cannot be used. Obviously, all the following results will also be true for the position of the rightmost zero in the FA-1f starting from a configuration which has a zero at the origin and is completely occupied in the right half-line.

The motion of the front has been analyzed in [Blo13, GLM15] for another one dimensional KCM, the East model, for which the constraint requires the site at the right of x to be empty: ergodicity of the measure seen from the front, law of large numbers, central limit theorem and cutoff results have been established. A key tool for the East model introduced in [AD02] and used in [Blo13, GLM15] for the study of the front, is the construction of a distinguished zero, a sort of moving boundary which induces local relaxation to equilibrium. This construction relies heavily on the oriented nature of the East constraint and cannot be extended to FA-1f and to generic KCM. Another consequence of the orientation is that the cutoff result in [GLM15] follows immediately from the central limit theorem for the front, while for FA-1f it would involve a more complex argument.

A sketch of the main step of our proof follows. Our first key result is to prove relaxation to equilibrium far behind the front (Theorem 5.1). In order to establish this result, we couple FA-1f dynamics with a sequence of threshold contact processes (Lemma 4.1) where zeros flip to ones at rate p without any constraint, and ones flip to zeros at rate q if and only if there is at least one nearest neighbor zero. The first contact process starts with a zero at the position of the front (namely at the origin), then if the contact process dies we restart a new one from the last killed zero. The threshold contact process is attractive, and it is well known that for q above a threshold $\bar{q} < 1$ the front of the process conditioned on survival moves ballistically. Due to the fact that there is no constraint for the contact process for the move $0 \rightarrow 1$, we can couple FA-1f and contact trajectories in such a way that FA-1f configurations contain more zeros than contact process configurations. Then, we can use the well-known behavior

of the contact process (ballistic motion of the front, shape theorem for the coupled zone) to guarantee enough zeros behind the front of FA-1f. This will be the work in Section 4. The construction is illustrated by the first simulation in Figure 1; we can see on the second one that the ballistic behavior of the FA-1f front seems still valid for some $q \leq \bar{q}$ but in this regime, the contact process does not give us any useful information. Afterward, we apply the techniques of [BCM+13] (Corollary 3.3) to prove relaxation to equilibrium using these zeros in Section 5. Once this result is established, we construct a coupling inspired by [Blo13, GLM15] to prove ergodicity of the process behind the front, namely convergence to the unique invariant measure for the process seen from the front (Section 6). This convergence result allows us to analyze the increments of the front (Section 7.1) and to deduce a law of large numbers. Finally, to study the fluctuations of the front, we generalize the strategy of [GLM15] which is in turn based on the result of Bolthausen [Bol82] which allows to establish a central limit theorem for random variables which are not stationary but satisfy a proper mixing condition (Theorem A.1).

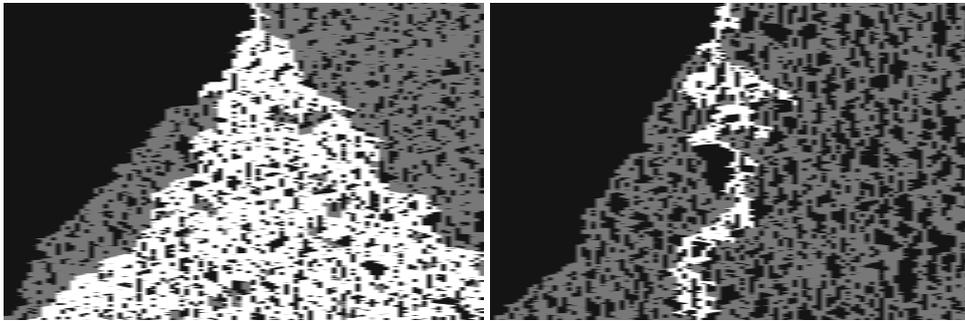

Figure 1: Simulation of FA-1f dynamics (gray points) coupled with restart threshold contact processes (white points). The first one is for $q > \bar{q}$ and the second one for $q < \bar{q}$.

2 Models and main results

2.1 The FA-1f process

Let $\Omega = \{0, 1\}^{\mathbb{Z}}$ be the space of configurations and

$$LO_0 = \{\sigma \in \Omega : \forall x < 0, \sigma(x) = 1, \sigma(0) = 0\}$$

be the subspace of configurations with a leftmost zero at the origin. For a configuration σ for which there exists $x \in \mathbb{Z}$ such that for every $y < x$, $\sigma(y) = 1$ and $\sigma(x) = 0$, we call x the *front* of configuration σ and we denote it by $X(\sigma)$.

For $\Lambda \subset \mathbb{Z}$ and $\sigma \in \Omega$, we denote by σ_Λ the restriction of σ to the set Λ . For $\sigma \in \Omega$ and $x \in \mathbb{Z}$, let σ^x be the configuration σ flipped at site x . We denote by θ_y the space shift operator of vector y : $\theta_y \sigma(x) = \sigma(x + y)$. We denote by δ^y the configuration such that $\delta^y(x) = 1$ for all $x \neq y$ and $\delta^y(y) = 0$.

The FA-1f dynamics on Ω are described by a Markov process with the following generator: for any local function f and any $\sigma \in \Omega$,

$$\mathcal{L}f(\sigma) = \sum_{x \in \mathbb{Z}} r(x, \sigma) (f(\sigma^x) - f(\sigma)) \tag{2.1}$$

where the rate $r(x, \sigma) = c(x, \sigma)(q\sigma(x) + p(1 - \sigma(x)))$ is the product between a constraint $c(x, \sigma)$ and a flip rate $q\sigma(x) + p(1 - \sigma(x))$. The constraint $c(x, \sigma) = 1 - \sigma(x - 1)\sigma(x + 1)$

requires at least one empty neighbor to allow the flip. The parameter p is the rate to update to 1 and the parameter $q = 1 - p$ is the rate to update to 0. Let σ_t be the configuration at time t starting from σ . When there is no confusion, $X(t)$ denotes the front of the configuration σ_t .

In the following, all constants may depend on q .

It is easy to verify that the FA-1f process is reversible w.r.t. $\mu := \text{Ber}(p)^{\otimes \mathbb{Z}}$.

2.2 An auxiliary process: the threshold contact process

We introduce a threshold contact process where the 0's are the infected points and the 1's are the healthy ones. Its dynamics on Ω is given by a Markov process with the following generator: for any local function f and any $\eta \in \Omega$,

$$\mathcal{L}' f(\eta) = \sum_{x \in \mathbb{Z}} r'(x, \eta)(f(\eta^x) - f(\eta))$$

where $r'(x, \eta) = c(x, \eta)q\eta(x) + p(1 - \eta(x))$. In this model, the constraint only applies to a flip $1 \rightarrow 0$. Namely, a 1 particle can flip to 0 only if one of its neighbor is 0; we interpret the state 0 as an infection that propagates by contact. The flip from 0 to 1 is a spontaneous recovery. Let η_t be the configuration at time t starting from η .

We define the extinction time of the threshold contact process by

$$\tau(\eta) = \inf\{t > 0, \forall x \in \mathbb{Z}, \eta_t(x) = 1\}, \tag{2.2}$$

that is the first time when the threshold contact process has no more zero (i.e. infected site). This state is absorbing for the process. If η_0 has a finite number of infected sites, $\tau(\eta)$ can be finite. For the FA-1f process, the corresponding extinction time is always infinite because a single zero can not disappear. If the event $\{\tau(\eta) = +\infty\}$ occurs we say that the contact process survives.

To ensure that the threshold contact process survives with positive probability, we need to suppose that $\frac{q}{p} > \lambda_c^{\text{TCP}}(\mathbb{Z})$ where the critical parameter of the threshold contact process $\lambda_c^{\text{TCP}}(\mathbb{Z})$ has an approximate value of 1.74 (cf. [BD88]). In the following we will suppose a stronger condition which is $\frac{q}{p} > 2\lambda_c(\mathbb{Z})$ where $\lambda_c(\mathbb{Z})$ is the critical parameter of the classical contact process and has an approximate value of 1.65 (cf. [BFM78]). This hypothesis allows us to use all the classical contact process estimates (cf. Appendix B) instead of having to reestablish them for the threshold contact process in the intermediate regime $\lambda \in (\lambda_c^{\text{TCP}}(\mathbb{Z}), 2\lambda_c(\mathbb{Z})]$. So, in this paper, we will consider $q > \bar{q}$ where

$$\bar{q} = \frac{2\lambda_c(\mathbb{Z})}{1 + 2\lambda_c(\mathbb{Z})}.$$

This corresponds approximately to taking $q \gtrsim 0.76$ rather than $q \gtrsim 0.63$.

2.3 Main results

Now we have the tools to enounce precisely the theorems that we will prove in this paper. The first one is the ergodicity of the process seen from the front. It will be proved thanks to a major coupling in Section 6.

Theorem 2.1. *Let $q > \bar{q}$. The process seen from the front has a unique invariant measure ν and, starting from every $\sigma \in LO_0$, it converges in distribution to ν in the following sense: there exist $d^* > 0$ and $c > 0$ (independent of σ) such that for t large enough*

$$\|\tilde{\mu}_t^\sigma - \nu\|_{[0, d^*t]} \leq e^{-ce^{(\log t)^{1/4}}},$$

where $\tilde{\mu}_t^\sigma$ is the distribution of the configuration seen from the front at time t starting from σ , i.e. $\theta_{X(\sigma_t)}\sigma_t$, and $\|\pi - \pi'\|_\Lambda$ denotes the total variation distance between the marginals of π and π' on Λ .

Remark 2.2. For every $\alpha > 0$, the velocity of convergence $e^{-e^{c(\log t)^{1/4}}}$ is less good than e^{-t^α} (which was the velocity obtained in the East case by [GLM15] for some $\alpha < 1/2$) but it is better than $e^{-(\log t)^{1/\alpha}}$ (and in particular better than any polynomial velocity).

The second one is a law of large numbers and a central limit theorem for the front.

Theorem 2.3. Let $q > \bar{q}$. There exists $s = s(q)$ and $v = v(q)$ such that for all $\sigma \in LO_0$

$$\frac{X(\sigma_t)}{t} \xrightarrow[t \rightarrow \infty]{} v \quad \mathbb{P}_\sigma - \text{almost surely}, \tag{2.3}$$

$$\frac{X(\sigma_t) - vt}{\sqrt{t}} \xrightarrow[t \rightarrow \infty]{d} \mathcal{N}(0, s^2) \quad \text{w.r.t. } \mathbb{P}_\sigma, \tag{2.4}$$

where $v = p \cdot \nu[\bar{\sigma}(1) = 0] - q$ is negative.

2.4 Graphical construction and basic coupling

We briefly recall here the graphical construction for the FA-1f and contact process, which allows to construct the two processes on the same probability space and to compare them pointwise. Throughout the text, \mathbb{N} denotes the set of positive integers. Let $\mathcal{C} = (B_{x,n}, E_{x,n})_{x \in \mathbb{Z}, n \in \mathbb{N}}$ be a collection of independent random variables, where for all $(x, n) \in \mathbb{Z} \times \mathbb{N}$, $B_{x,n} \sim \text{Ber}(p)$, $E_{x,n} \sim \text{Exp}(1)$. These variables are interpreted as follows: with each site $x \in \mathbb{Z}$ we associate a sequence of exponential clock rings given by the $\sum_{k=1}^n E_{x,k}$, $n \in \mathbb{N}$, and with the clock ring at time $\sum_{k=1}^n E_{x,k}$ we associate the Bernoulli variable $B_{x,n}$. Starting from configurations $\sigma, \eta \in \Omega$, we construct a FA-1f process $(\sigma_t)_{t \geq 0}$ and a (threshold) contact process $(\eta_t)_{t \geq 0}$ using the same collection \mathcal{C} . When a clock rings at x , we update each process at this site to the associated Bernoulli variable, provided the constraint of the process is satisfied (for instance, if the Bernoulli variable is 1, the contact process automatically updates, while the FA-1f needs at least one empty neighbor). We call $(\sigma_t, \eta_t)_{t \geq 0}$ the basic coupling started from (σ, η) using \mathcal{C} . We denote by \mathbb{P}, \mathbb{E} the associated probability and expectation. This probability space allows us to construct the processes with any initial configuration simultaneously. We will denote by $\mathbb{P}_{\sigma, \eta}$ (respectively $\mathbb{P}_\sigma, \mathbb{P}_\eta$) the associated probability to the initial configuration (σ, η) (respectively the projected probabilities).

The following property will be our main tool to guarantee a minimal quantity of zeros in the FA-1f process.

Lemma 2.4. If $\sigma \leq \eta$ (pointwise), with the above construction, we have a.s.

$$\forall t \geq 0, \quad \sigma_t \leq \eta_t.$$

Proof. It is not difficult to check that every possible transition preserves the order. \square

It will also be useful to define a (space) shift operation on the collection \mathcal{C} by

$$\theta_y \mathcal{C} = (B_{y+x,n}, E_{y+x,n})_{x \in \mathbb{Z}, n \in \mathbb{N}}.$$

To quantify the amount of zeros we will introduce the following event. A 0-gap is an interval without zeros.

Definition 2.5. Let L, M, l be three positive numbers.

$$\begin{aligned} \mathcal{H}(L, L + M, l) &= \{ \text{There is no 0-gap of length } l \text{ in the box } [L, L + M] \} \\ &= \{ \sigma : \forall y \in [L, L + M - l + 1], \exists z \in [y, y + l - 1], \sigma(z) = 0 \}. \end{aligned}$$

If $l \leq M + 1$, it is also equivalent to say that there is at least one zero in the box and the maximal distance between two zeros in the box $[L, L + M]$ is less than l .

2.5 Finite speed propagation

Classically, this type of graphical construction implies finite speed of propagation in the following sense. For $x, y \in \mathbb{Z}$ and $t > 0$, we denote by

$$F(x, y, t) = \{\text{before time } t \text{ there is a sequence of successive rings linking } x \text{ to } y\},$$

$$\tilde{F}(x, y, t) = \{\exists z \text{ between } x \text{ and } y \text{ s.t. } F(x, z, t) \cap F(y, z, t)\}.$$

Above, a sequence of successive rings linking x and y means that (if e.g. $x < y$) there is a clock ring at site x , and then at site $x + 1$ and so on until y is reached. Standard results on Poisson point processes imply the following.

Lemma 2.6. *There exists a constant \bar{v} (which is bigger than 1) such that, for every t and $x, y \in \mathbb{Z}$ such that $|x - y| \geq \bar{v}t$ then*

$$\mathbb{P}(F(x, y, t)) \leq \mathbb{P}(\tilde{F}(x, y, t)) \leq e^{-|x-y|}.$$

This has immediate implications for the maximal velocity of the front in the FA-1f process and for the propagation of the contact process.

Corollary 2.7. *For all $\sigma \in LO_0$, $c \geq \bar{v}$,*

$$\mathbb{P}_\sigma(|X(\sigma_t)| \geq ct) \leq e^{-ct}, \tag{2.5}$$

and $\mathbb{P}_{\delta^0}(\exists y : |y| \geq ct \text{ and } \eta_t(y) = 0) \leq e^{-ct}.$ (2.6)

3 Relaxation in FA-1f

In this section, we collect results about the relaxation to equilibrium (i.e. to $\mu = \text{Ber}(p)^{\otimes \mathbb{Z}}$) of the FA-1f process. These can be deduced from the proofs in [BCM+13] as explained below.

Proposition 3.1. *Let $q > 1/2$ and $t > 0$. Let $K > 0$, f a bounded function with support contained in $[-K, K]$ such that $\mu(f) = 0$. Define $\Lambda := [-K - \bar{v}t, K + \bar{v}t] \cap \mathbb{Z}$. Decompose $\Lambda = \sqcup_{i=1}^n \Lambda_i$ with Λ_i disjoint intervals in \mathbb{Z} such that for all $i = 1, \dots, n$ $|\Lambda_1| \leq |\Lambda_i| \leq 2|\Lambda_1|$. Choose $\theta > 1$ satisfying $\frac{\theta}{\theta+1} < q$. Then there exists $c = c(q, \theta) > 0$ such that for all initial configuration $\sigma \in \mathcal{H}(-K - \bar{v}t, K + \bar{v}t, |\Lambda_1|/8)$,*

$$|\mathbb{E}_\sigma[f(\sigma_t)]| \leq c\|f\|_\infty \left(\exp\left(-c^{-1}t + c|\Lambda|e^{-\frac{t}{c|\Lambda|}}\right) + tn|\Lambda|\theta^{-|\Lambda_1|/4} \left(c + \theta^{|\Lambda_1|/8} \right) + ne^{-q|\Lambda_1|} + |\Lambda|e^{-t/3} \right).$$

A similar result holds for the FA-1f dynamics in finite volume.

Proposition 3.2. *Let $q > 1/2$ and $t > 0$. Let $K > 0$, f a bounded function with support contained in $\Lambda := [-K, K]$ such that $\mu(f) = 0$. Decompose $\Lambda = \sqcup_{i=1}^n \Lambda_i$ with Λ_i disjoint intervals in \mathbb{Z} such that for all $i = 1, \dots, n$ $|\Lambda_1| \leq |\Lambda_i| \leq 2|\Lambda_1|$. Choose $\theta > 1$ satisfying $\frac{\theta}{\theta+1} < q$. Then there exists $c = c(q, \theta) > 0$ such that for all initial configuration $\sigma \in \mathcal{H}(-K, K, |\Lambda_1|/8)$,*

$$|\mathbb{E}_\sigma[f(\sigma_t^\Lambda)]| \leq c\|f\|_\infty \left(\exp\left(-c^{-1}t + c|\Lambda|e^{-\frac{t}{c|\Lambda|}}\right) + tn|\Lambda|\theta^{-|\Lambda_1|/4} \left(c + \theta^{|\Lambda_1|/8} \right) + ne^{-q|\Lambda_1|} + |\Lambda|e^{-t/3} \right),$$

where $(\sigma_t^\Lambda)_{t \geq 0}$ denotes the FA-1f process in Λ with zero boundary condition.

Proof of Proposition 3.1. The proof of this result is essentially contained in [BCM+13]. We reproduce here the arguments that we need.

First, let $(\sigma_t^\Lambda)_{t \geq 0}$ denote the FA-1f process restricted to $\Lambda = [-K - \bar{v}t, K + \bar{v}t] \cap \mathbb{Z}$ with empty boundary condition and started from σ_Λ . By finite speed of propagation, we have, for f bounded with support in $[-K, K]$

$$|\mathbb{E}_\sigma[f(\sigma_t)] - \mathbb{E}_{\sigma_\Lambda}[f(\sigma_t^\Lambda)]| \leq 4\|f\|_\infty e^{-t}. \tag{3.1}$$

Also, Proposition 5.1 in [BCM+13] ensures that for some $c = c(q) < \infty$,

$$|\mathbb{E}_{\sigma_\Lambda}[f(\sigma_t^\Lambda)]| \leq c\|f\|_\infty \left(ne^{-q|\Lambda_1|} + t|\Lambda| \sup_{s \in [0,t]} \mathbb{P}_{\sigma_\Lambda}(\sigma_s^\Lambda \notin \mathcal{A}) + |\Lambda| \exp(-t/3) + \exp\left(-t/c + c|\Lambda|e^{-\frac{t}{c|\Lambda_1|}}\right) \right),$$

where $\mathcal{A} = \bigcap_{i=1}^n \{\sigma \in \{0, 1\}^\Lambda : \sum_{x \in \Lambda_i} (1 - \sigma(x)) \geq 2\}$ is the event that there are at least two zeros in each Λ_i .

It remains to control $\sup_{s \in [0,t]} \mathbb{P}_{\sigma_\Lambda}(\sigma_s^\Lambda \notin \mathcal{A})$. Here we need to recall another result from [BCM+13]. For $x \in \Lambda$, $\sigma \in \{0, 1\}^\Lambda$, let $\xi^x(\sigma)$ be the minimal distance from x to an empty site in σ :

$$\xi^x(\sigma) = \min\{|x - y| : y \in \Lambda \cup \partial\Lambda \text{ s.t. } \sigma(y) = 0\},$$

with the convention that $\sigma(y) = 0$ for $y \in \partial\Lambda$ (recall that σ^Λ is defined as the FA-1f process in Λ with empty boundary conditions). Thanks to a comparison of ξ^x with a random walk drifted towards 0, Proposition 4.1 in [BCM+13] establishes that for all $x \in \Lambda$, $\theta \geq 1$ such that $q \in (\theta/(\theta + 1), 1]$, $\sigma \in \{0, 1\}^\Lambda$, $t \geq 0$,

$$\mathbb{E}_\sigma \left[\theta^{\xi^x(\sigma^\Lambda)} \right] \leq \theta^{\xi^x(\sigma)} e^{-\lambda t} + \frac{q}{q(\theta + 1) - \theta}, \tag{3.2}$$

where $\lambda = \frac{\theta^2 - 1}{\theta} \left(q - \frac{\theta}{\theta + 1} \right) > 0$.

Partition each Λ_i into two intervals Λ_i^+, Λ_i^- of length at least $|\Lambda_1|/2$, centered respectively in x_i^+, x_i^- . If $\sigma \notin \mathcal{A}$, necessarily there exists $i \in \{1, \dots, n\}$ such that either $\sigma|_{\Lambda_i^+} \equiv 1$ or $\sigma|_{\Lambda_i^-} \equiv 1$. In particular, either $\xi^{x_i^+}(\sigma)$ or $\xi^{x_i^-}(\sigma)$ is larger than $|\Lambda_1|/4$. Therefore, for all $s \leq t$,

$$\begin{aligned} \mathbb{P}_{\sigma_\Lambda}(\sigma_s^\Lambda \notin \mathcal{A}) &\leq \sum_{i=1}^n \left(\mathbb{P}_{\sigma_\Lambda}(\xi^{x_i^+}(\sigma_s^\Lambda) \geq |\Lambda_1|/4) + \mathbb{P}_{\sigma_\Lambda}(\xi^{x_i^-}(\sigma_s^\Lambda) \geq |\Lambda_1|/4) \right) \\ &\leq \sum_{i=1}^n \theta^{-|\Lambda_1|/4} \left(\mathbb{E}_{\sigma_\Lambda} \left[\theta^{\xi^{x_i^+}(\sigma_s^\Lambda)} \right] + \mathbb{E}_{\sigma_\Lambda} \left[\theta^{\xi^{x_i^-}(\sigma_s^\Lambda)} \right] \right) \\ &\leq 2n\theta^{-|\Lambda_1|/4} \left(\theta^{|\Lambda_1|/8} + c \right) \end{aligned}$$

for some constant c depending on q, θ . The last inequality comes from (3.2) and the assumption on the maximal distance between two zeros in σ . □

Proof of Proposition 3.2. The only change with respect to the above proof is that we don't need the finite volume propagation step (3.1). □

Corollary 3.3. *Let $q > 1/2$ and $t > 0$. Let $K > 0$, f a bounded function with support contained in $[-K, K]$ such that $\mu(f) = 0$. If $K \leq e^{t^\alpha}$ with $\alpha \in (0, 1/2)$, there exists $c' = c'(\alpha, q) > 0$ such that,*

- if $\sigma \in \mathcal{H}(-K - \bar{v}t, K + \bar{v}t, \sqrt{t})$,

$$|\mathbb{E}_\sigma[f(\sigma_t)]| \leq \frac{1}{c'} \|f\|_\infty e^{-c' \sqrt{t}}; \tag{3.3}$$

- if $\sigma \in \mathcal{H}(-K, K, \sqrt{t})$,

$$|\mathbb{E}_\sigma[f(\sigma_t^{[-K, K]})]| \leq \frac{1}{c'} \|f\|_\infty e^{-c' \sqrt{t}}, \tag{3.4}$$

where $(\sigma_t^{[-K, K]})_{t \geq 0}$ denotes the FA-1f process in $[-K, K]$ with zero boundary condition.

The assumption $K \leq e^{t^\alpha}$ with $\alpha < 1/2$ represents in fact the largest support we can consider for f such that the estimate in Proposition 3.1 is useful. Indeed, it does not give a vanishing estimate for $K = e^{\sqrt{t}}$.

Proof. It suffices to choose $|\Lambda_1| = 8\sqrt{t}$ and apply Propositions 3.1 and 3.2. □

4 Coupling between FA-1f and contact process

We wish to exploit the comparison result between the FA-1f and contact processes (see Lemma 2.4) to guarantee a sufficient number of zeros for the FA-1f dynamics. To this purpose, since the contact process can die, we will need first to do a restart argument.

4.1 Restart argument

Lemma 4.1. *Let $q > \bar{q}$. For any $\sigma \in LO_0$, there exist a process $(\sigma_t, \eta_t)_{t \geq 0}$ taking values in Ω^2 and two random variables T and Y taking respectively their values in \mathbb{R}^+ and \mathbb{Z} such that*

1. $(\sigma_t)_{t > 0}$ is an FA-1f process starting from $\sigma \in LO_0$,
2. $\forall t > 0, \forall x \in \mathbb{Z}, \sigma_t(x) \leq \eta_t(x)$,
3. $(\eta_{T+t}(Y + \cdot))_{t > 0}$ is a surviving threshold contact process starting from δ^0 .

Moreover, T and $|Y|$ have exponentially decaying tail probabilities.

Proof. The idea is to couple a FA-1f process with a contact process and to restart the second one each time that it vanishes. Eventually, the contact process will survive (because $q > \bar{q}$) and the space-time point (Y, T) corresponding to the origin of this surviving contact process is not very far from the origin. The procedure is illustrated by Figure 2.

Let $(\mathcal{C}^{(i)})_{i \in \mathbb{N}}$ be a sequence of independent copies of the collection described in Section 2.4 and \mathbb{P} their distribution. For $i \in \mathbb{N}$, let $\eta^{(i)} = (\eta_t^{(i)})_{t \geq 0}$ be the contact process started from δ^0 constructed with $\mathcal{C}^{(i)}$. Further let $U_i = \tau(\eta^{(i)})$ be the extinction time of $\eta^{(i)}$ as defined in (2.2). The random variables $(U_i)_{i \in \mathbb{N}}$ are independent and identically distributed and, by our choice of q , we have $\mathbb{P}(U_1 = \infty) > 0$. Let

$$L = \min\{i \in \mathbb{N}, U_i = \infty\}.$$

The random variable L has geometric distribution. Moreover, conditionally on $\{L = l\}$, (U_1, \dots, U_{l-1}) are i.i.d. with the same distribution as U_1 conditioned on $U_1 < \infty$. Let

$$T = \sum_{i=1}^{L-1} U_i,$$

with $T = 0$ if $L = 1$. Then T has exponentially decaying tail probabilities. Indeed, from Estimate (B.3) (cf. Appendix B), we have for $t > 0$

$$\mathbb{P}(t < U_i < \infty) = \mathbb{P}(t < \tau^{\{0\}} < \infty) \leq C_1 \exp(-C_2 t).$$

FA-1f front evolution

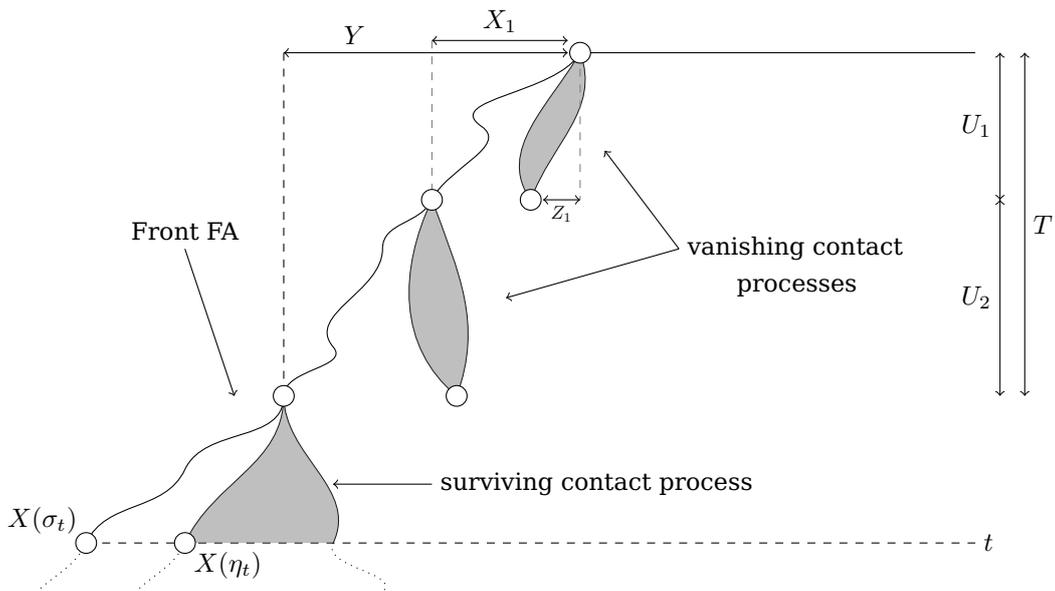

Figure 2: Restart procedure, coupling between FA-1f and surviving contact process.

So, we can choose β_1 and β_2 such that $\mathbb{E}[e^{\beta_1(L-1)}] < \infty$ and $\mathbb{E}[e^{\beta_2 U_1} \mid U_1 < \infty] < e^{\beta_1}$. We have that

$$\mathbb{E}[e^{\beta_2 T}] = \mathbb{E}\left[\mathbb{E}\left[e^{\beta_2 \sum_{i=1}^{L-1} U_i} \mid L\right]\right] = \mathbb{E}\left[\mathbb{E}\left[e^{\beta_2 U_1} \mid U_1 < \infty\right]^{L-1}\right] \leq \mathbb{E}\left[e^{\beta_1(L-1)}\right] < \infty.$$

We construct recursively a sequence of processes $(\sigma_t^{[i]}, \eta_t^{[i]})_{t \geq 0}$ and random variables $X_i \in \mathbb{Z}$ for $i \in \mathbb{N}$.

1. Let $(\sigma_t^{[1]}, \eta_t^{[1]})_{t \geq 0}$ be the basic coupling started from (σ, δ^0) using $\mathcal{C}^{(1)}$. We define $X_1 := X(\sigma_{U_1})$ if $U_1 < \infty$ and 0 else.
2. Assuming $(\sigma_t^{[i]}, \eta_t^{[i]})_{t \geq 0}$ and X_i have been constructed, we define $(\sigma_t^{[i+1]}, \eta_t^{[i+1]})_{t \geq 0}$ as follows.
 - If $T_i := \sum_{j=1}^i U_j = \infty$ then $(\sigma_t^{[i+1]}, \eta_t^{[i+1]})_{t \geq 0} := (\sigma_t^{[i]}, \eta_t^{[i]})_{t \geq 0}$ and $X_{i+1} := X_i$.
 - Else, let $(\sigma_t^{[i+1]}, \eta_t^{[i+1]}) = (\sigma_t^{[i]}, \eta_t^{[i]})$ for $t < T_i$ and $(\sigma_{T_i+t}^{[i+1]}, \eta_{T_i+t}^{[i+1]})_{t \geq 0}$ be the basic coupling started from $(\sigma_{T_i}^{[i]}, \delta^{X_i})$ using $\theta_{X_i} \mathcal{C}^{(i+1)}$ the spatial translation by X_i of the collection $\mathcal{C}^{(i+1)}$ (in particular U_{i+1} is the extinction time of $(\eta_{T_i+t}^{[i+1]})_{t \geq 0}$). We choose $X_{i+1} := X(\sigma_{T_i+U_{i+1}}^{[i+1]})$ if $U_{i+1} < \infty$ and $X_{i+1} := X_i$ else.

Since L has geometric distribution, the algorithm fixates almost surely in finite time: for $i \geq L$, $(\sigma_t^{[i+1]}, \eta_t^{[i+1]})_{t \geq 0} = (\sigma_t^{[i]}, \eta_t^{[i]})_{t \geq 0}$. This allows to define $(\sigma_t, \eta_t)_{t \geq 0}$ as $(\sigma_t^{[L]}, \eta_t^{[L]})_{t \geq 0}$ and $Y = X_{L-1}$. Moreover, since the U_i are stopping times, $(\sigma_t)_{t \geq 0}$ is a FA-1f process started from σ . We also have immediately that $(\eta_{T+t}(Y + \cdot))_{t \geq 0}$ is a surviving threshold contact process starting from δ^0 . Finally, Lemma 2.4 implies that $\sigma_t \leq \eta_t$ for all $t \geq 0$; indeed, by definition, X_i is a zero of the configuration $\sigma_{T_i}^{[i]}$ and therefore $\sigma_{T_i}^{[i]} \leq \delta^{X_i}$ for $i \leq L - 1$.

It remains to show that Y has exponentially decaying tail probability. To that end, for $i \leq L - 1$ let Z_i be the position of the unique zero in $\eta_{T_i}^-$. We have that $X_i \leq Z_i + 1$. Indeed, by definition of Z_i , $\eta_{U_i}^-(Z_i) = \sigma_{U_i}^-(Z_i) = 0$. If $\sigma_{U_i}^-(Z_i - 1) = \sigma_{U_i}^-(Z_i + 1) = 1$ then $\sigma_{U_i}(Z_i) = 0$ because the FA-1f constraint is not satisfied and the zero at position Z_i

at time U_i^- can not update. If $\sigma_{U_i^-}(Z_i - 1)$ or $\sigma_{U_i^-}(Z_i + 1)$ is equal to 0, it is still equal to 0 at time U_i because there is already a Poisson clock ringing at position Z_i at time U_i , so $X_i \leq Z_i + 1$. Thus,

$$Y = X_{L-1} \leq \sum_{i=1}^{L-1} (Z_i - X_{i-1}) + L,$$

with $X_0 = 0$. Conditionally on the event $\{L = l\}$, the random variables $\{Z_i - X_{i-1}, i = 1, \dots, l-1\}$ are independent and have the same distribution: they represent the expansion of a non-surviving contact process. For $t > 0$,

$$\begin{aligned} \mathbb{P}(T \leq at, |Y| > t, L \leq t/2) &\leq \mathbb{P}\left(\sum_{i=1}^{L-1} U_i \leq at, \left|\sum_{i=1}^{L-1} Z_i - X_{i-1}\right| > t/2\right) \\ &\leq \sum_{l=1}^{\infty} \mathbb{P}(L = l) \mathbb{P}\left(\sum_{i=1}^{l-1} U_i \leq at, \left|\sum_{i=1}^{l-1} Z_i - X_{i-1}\right| > t/2 \mid L = l\right) \\ &\leq A \exp(-Bt) \end{aligned}$$

using the ‘at most linearity’ (2.6) of the contact process with $a < \frac{1}{2v}$. We conclude using the exponentially decaying tail of L and T :

$$\begin{aligned} \mathbb{P}(|Y| > t) &\leq \mathbb{P}(T > at) + \mathbb{P}(L > t/2) + \mathbb{P}(T \leq at, |Y| > t, L \leq t/2) \\ &\leq A \exp(-Bt). \end{aligned} \quad \square$$

4.2 Consequences of the coupling

The first consequence of the previous coupling is the ‘at least linear growth’ of the front of the FA-1f process.

Corollary 4.2. *Let $q > \bar{q}$. There exists $v > 0$ and $A, B > 0$ such that for every $\sigma \in LO_0$ and $t > 0$,*

$$\mathbb{P}(X(\sigma_t) > -vt) \leq A \exp(-Bt).$$

Proof. Denote by v_{cp} the velocity of the contact process (see Theorem B.1). Choose $\underline{v} = v_{cp}/2$. Let $(\sigma_t, \eta_t)_{t \geq 0}$, T and Y be the objects defined in Lemma 4.1. We denote by $X(\eta_t)$ the position of the leftmost zero at time t in a contact process started from δ^0 . For every $t > 0$, $c \in (0, 1)$,

$$\begin{aligned} \mathbb{P}(X(\sigma_t) > -\underline{v}t, 0 \leq T \leq ct, Y \leq ct) &\leq \mathbb{P}(X(\eta_t) - Y > -(v+c)t, (1-c)t \leq t - T \leq t) \\ &\leq \mathbb{P}\left(X(\eta_{T+(t-T)}(Y + \cdot)) > -\frac{v+c}{1-c}(t-T), (1-c)t \leq t - T \leq t\right) \\ &\leq \sup_{u \in [(1-c)t, t]} \mathbb{P}\left(X(\eta_{T+u}(Y + \cdot)) > -\frac{v+c}{1-c}u\right) \\ &\leq \sup_{u \in [(1-c)t, t]} A \exp(-Bu) = A \exp(-B't) \end{aligned}$$

where we used that $\sigma_t \leq \eta_t$ (and therefore $X(\sigma_t) \leq X(\eta_t)$) in the first line. We choose $c > 0$ such that $\frac{v+c}{1-c} < v_{cp}$ and apply (B.4) of Theorem B.1 to the surviving contact process $\tilde{\eta}_u(\cdot) = \eta_{T+u}(Y + \cdot)$ and we bound the last probability. The fact that T and $|Y|$ have exponentially decaying tails allows to conclude. \square

The second consequence of the coupling is to guarantee a minimal quantity of zeros around the origin in the FA-1f process.

Corollary 4.3. *Let $q > \bar{q}$. There exist $c_1, c_2 > 0$ such that for any $\sigma \in LO_0$, $t > 0$, if $\sigma(x) = 0$ then we have*

$$\mathbb{P}_\sigma(\sigma_t \notin \mathcal{H}(x - vt, x + vt, l)) \leq c_1 t \exp(-c_2(t \wedge l)).$$

Proof. Let us do the proof for $x = 0$. We use again the coupling from Lemma 4.1. For $t > 0$, $\alpha \leq v_{cp} - v$,

$$\begin{aligned} & \mathbb{P}_\sigma(\sigma_t \notin \mathcal{H}(-vt, vt, l), T \leq t/2, |Y| \leq \alpha t) \\ & \leq \mathbb{P}(\exists y \in [Y - (v + \alpha)t, Y + (v + \alpha)t - l + 1] \text{ s.t. } \eta_t([y, y + l - 1]) \equiv 1, T \leq t/2) \\ & \leq \sum_{y=-(v+\alpha)t}^{(v+\alpha)t} \mathbb{P}(\forall z \in [y, y + l - 1], \eta_{T+(t-T)}(Y + z) = 1, t/2 \leq t - T \leq t) \\ & \leq 2v_{cp}t \int_{u=t/2}^t A \exp(-B(u \wedge l)) d\mathbb{P}(T = u - t), \\ & \leq A't \exp(-B'(t \wedge l)), \end{aligned}$$

where we applied the Corollary B.2 to the surviving contact process $\tilde{\eta}_u(\cdot) = \eta_{T+u}(Y + \cdot)$ with $v \leq v_{cp}$. The fact that T and $|Y|$ have exponentially decaying tails allows to conclude. If $x \neq 0$ we can do the same proof but we have to start the coupling from the point x and to restart from the closest zero (instead of the front) when the contact process dies. \square

4.3 Zeros lemma

In the following lemma we use repeatedly Corollary 4.3 to control the probability that, at time s , at distance L from the front and over a distance M , we have no 0-gap larger than l .

Lemma 4.4. *Let $q > \bar{q}$. Let $s, l, M, L > 0$ and $\sigma \in LO_0$.*

1. *If $L + M \leq 2vs$ then there exists $c > 0$ depending only on p such that*

$$\mathbb{P}_\sigma(\theta_{X(s)}\sigma_s \notin \mathcal{H}(L, L + M, l)) \leq (L + M)^2 \exp(-c(L \wedge l)).$$

2. *If $L + M \geq 2vs$ and $\sigma \in \mathcal{H}(0, L + M, 2vs)$ then there exists $c > 0$ such that*

$$\mathbb{P}_\sigma(\theta_{X(s)}\sigma_s \notin \mathcal{H}(L, L + M, l)) \leq \frac{s^2}{L} \exp(-c(L \wedge l)) + Ms \exp(-c(s \wedge l)).$$

Proof. The strategy is the following: we consider a number of zeros which we know are present in the dynamics, either because they are present in the initial configuration or because they are well-chosen intermediate positions occupied by the front. For each of these zeros, we use Corollary 4.3 to guarantee that at time s , a given interval around them contains no gap larger than $l/2$. We then control that w.h.p. the different intervals thus obtained cover $[X(s) + L, X(s) + L + M]$, and therefore $\theta_{X(s)}\sigma_s \in \mathcal{H}(L, L + M, l)$. The technique is illustrated by Figure 3.

Let us define the intermediate times we consider. Let

$$\begin{aligned} \Delta &= \frac{L}{\bar{v} - v} \wedge s, \\ n &= \left\lceil \frac{(s - \Delta)(\bar{v} - v)}{2v\Delta} \right\rceil, \\ \Delta' &= \frac{s - \Delta}{n}, \\ s_i &= i\Delta' \text{ for } i \in \{0, \dots, n\}. \end{aligned}$$

FA-1f front evolution

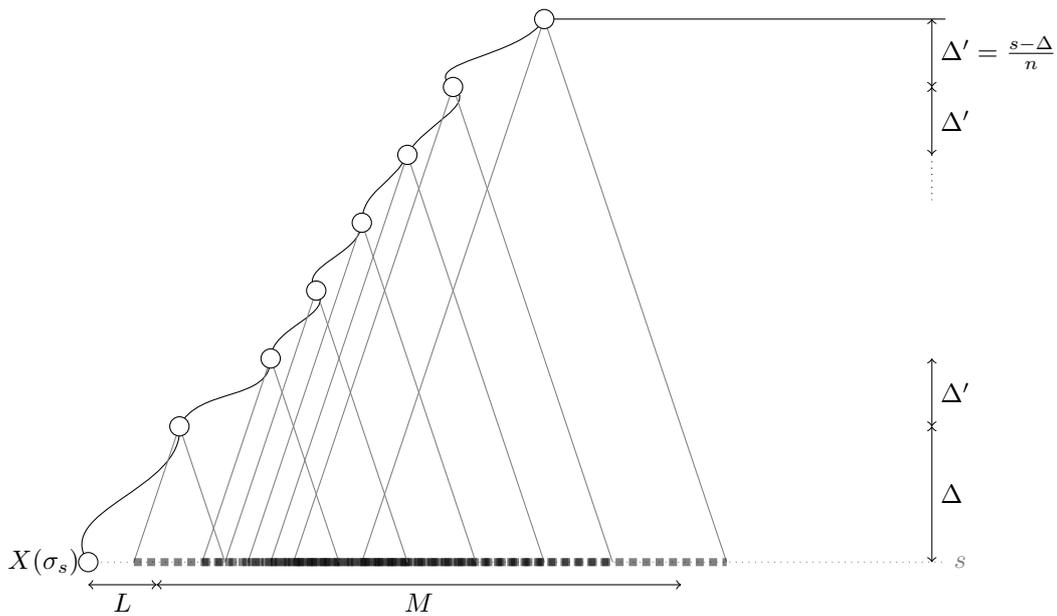

Figure 3: There is no 0-gap bigger than ℓ on the interval $[L, L + M]$ seen from the front.

For $i \in \{0, \dots, n\}$, by Corollary 4.3 and the Markov property applied at time s_i , for some constants $C, c > 0$

$$\mathbb{P}_\sigma(\sigma_s \notin \mathcal{H}(X(s_i) - \underline{v}(s - s_i), X(s_i) + \underline{v}(s - s_i), l/2)) \leq C(s - s_i)e^{-c(s-s_i)\wedge l},$$

i.e. $[X(s_i) - \underline{v}(s - s_i), X(s_i) + \underline{v}(s - s_i)]$ contains no gap larger than $l/2$ with high probability.

In case 2, we also need to use the zeros of the initial configuration. Let $0 =: x_0 < x_1 < \dots < x_m$ be the ordered set of zeros located between 0 and $L + M$ in the initial configuration σ . Then by Corollary 4.3, for $i \in \{0, \dots, m\}$,

$$\mathbb{P}_\sigma(\sigma_s \notin \mathcal{H}(x_i - \underline{v}s, x_i + \underline{v}s, l/2)) \leq Cse^{-c(s\wedge l)},$$

i.e. $[x_i - \underline{v}s, x_i + \underline{v}s]$ contains no gap larger than $l/2$ with high probability.

The next step is to control the respective positions of the intervals we introduced to check that with high probability they cover $[X(s) + L, X(s) + L + M]$. Let us consider for all $i \in \{0, \dots, n - 1\}$ the events that

$$\underline{v}\Delta \leq X(s_n) - X(s) \leq \bar{v}\Delta \tag{4.1}$$

$$\underline{v}\Delta' \leq X(s_i) - X(s_{i+1}) \leq \bar{v}\Delta'. \tag{4.2}$$

Fix $k \in \{0, \dots, n\}$. With our choice of Δ and n , if (4.1) and (4.2) hold for $i \in \{n - k, \dots, n - 1\}$, we have for $i \in \{n - k, \dots, n - 1\}$

$$X(s_n) - \underline{v}\Delta \leq X(s) + L, \tag{4.3}$$

$$X(s_i) - \underline{v}(\Delta + (n - i)\Delta') \leq X(s_{i+1}) + \underline{v}(\Delta + (n - i - 1)\Delta'), \tag{4.4}$$

$$X(s) + 2\underline{v}(\Delta + k\Delta') \leq X(s_{n-k}) + \underline{v}(s - s_{n-k}). \tag{4.5}$$

To derive (4.4) we used that $\bar{v}\Delta' \leq \underline{v}(2\Delta + \Delta')$. These equations in turn imply that

$\bigcup_{i=n-k}^n [X(s_i) - \underline{v}(s - s_i), X(s_i) + \underline{v}(s - s_i)]$ is a covering of $[X(s) + L, X(s) + 2\underline{v}(\Delta + k\Delta')]$.

Similarly, if $\sigma \in \mathcal{H}(0, L + M, 2vs)$ then we know that $x_{i+1} - x_i \leq 2vs$ for $i \in \{0, \dots, m - 1\}$ and $x_m \geq L + M - 2vs$. Consequently, if (4.1) and (4.2) hold for all $i \in \{0, \dots, n\}$ then we have

$$\bigcup_{i=0}^n [X(s_i) - \underline{v}(s - s_i), X(s_i) + \underline{v}(s - s_i)] \cup \bigcup_{j=1}^m [x_j - \bar{v}s, x_j + \bar{v}s] \supset [X(s) + L, L + M - \underline{v}s].$$

Case 1: $L + M \leq 2vs$

Choose $k = \lceil \frac{L+M-2v\Delta}{2v\Delta'} \rceil$. Then $2v(\Delta + k\Delta') \geq L + M$, and the above arguments and the bounds we have on the speed of the front yield

$$\begin{aligned} & \mathbb{P}_\sigma(\theta_{X(s)}\sigma_s \notin \mathcal{H}(L, L + M, l)) \\ & \leq \mathbb{P}_\sigma \left(\sigma_s \in \bigcup_{i=n-k}^n \mathcal{H}(X(s_i) - \underline{v}(s - s_i), X(s_i) + \underline{v}(s - s_i), l/2)^c \right) \\ & \quad + \mathbb{P}_\sigma((4.1) \text{ is not satisfied}) \\ & \quad + \mathbb{P}_\sigma(\exists i \in \{n - k, \dots, n - 1\} \text{ for which (4.2) is not satisfied}) \\ & \leq k(k\Delta' + \Delta)c_1 \exp(-c_2((\Delta' + \Delta) \wedge l)) \\ & \quad + A \exp(-B\Delta) + kA \exp(-B\Delta') \\ & \leq c'_1(L + M)^2 \exp(-c'_2(L \wedge l)), \end{aligned}$$

where we used Corollary 4.2 and Lemma 2.6.

Case 2: $L + M \geq 2vs$

Our arguments imply that

$$\begin{aligned} & \mathbb{P}_\sigma(\theta_{X(s)}\sigma_s \notin \mathcal{H}(L, L + M, l)) \\ & \leq \mathbb{P}_\sigma \left(\sigma_s \in \bigcup_{i=0}^n \mathcal{H}(X(s_i) - \underline{v}(s - s_i), X(s_i) + \underline{v}(s - s_i), l/2)^c \right) \\ & \quad + \mathbb{P}_\sigma \left(\sigma_s \in \bigcup_{i=1}^m \mathcal{H}(x_i - \underline{v}s, x_i + \underline{v}s, l/2)^c \right) \\ & \quad + \mathbb{P}_\sigma((4.1) \text{ is not satisfied}) \\ & \quad + \mathbb{P}_\sigma(\exists i \in \{0, \dots, n - 1\} \text{ for which (4.2) is not satisfied}) \\ & \leq c'_1 \frac{s^2}{L} \exp(-c'_2(L \wedge l)) + Ms \exp(-c(s \wedge l)). \quad \square \end{aligned}$$

5 Relaxation far from the front

Now, we will use the bounds on the speed of the front ((2.5) and Corollary 4.2) and relaxation results (Corollary 3.3) to prove a relaxation far from the front. To do that we need to decorrelate the front trajectory from the interval in which we want to relax.

Theorem 5.1. *Let $q > \bar{q}$ and $\sigma \in LO_0$. Let $\alpha < 1/2$ and $\delta > 0$. There exists $c > 0$ such that for any $M \leq e^{\delta t^\alpha}$, any f with support in $[0, M]$, $\mu(f) = 0$ and $\|f\|_\infty \leq 1$, if $\sigma \in \mathcal{H}(\underline{v}t, M + (4\bar{v} - \underline{v})t, \sqrt{t})$, then*

$$|\mathbb{E}_\sigma [f(\theta_{X(\sigma_t)+3\bar{v}t}\sigma_t)]| \leq e^{-c\sqrt{t}}.$$

Remark 5.2. The proof strategy of the equivalent theorem in [Blo13] combined with Lemma 4.4 and Corollary 3.3 would also allow us to give a result of the type “in the box $[L, L + M]$ seen from the front, the distribution is within $e^{-c\sqrt{L \wedge t}}$ of μ in total variation

distance”, under suitable hypotheses on the initial configuration (depending on the respective regimes of L, t, M). A proper statement would however be too technical for the purpose of the present paper and we restrict to the above.

Proof. Using Corollary 4.2 and Equation (2.5) we can write that

$$\mathbb{E}_\sigma [f(\theta_{X(\sigma_t)+3\bar{v}t}\sigma_t)] = \sum_{y=\underline{v}t}^{\bar{v}t} \mathbb{E}_\sigma [\mathbb{1}_{X(\sigma_t)=-y} f(\theta_{3\bar{v}t-y}\sigma_t)] + O(e^{-\gamma t}).$$

By finite speed of propagation, we have with probability $1 - O(e^{-t})$

$$\max_{u \in [0,t]} |X(\sigma_u)| \leq \bar{v}t.$$

So, for $y \leq \bar{v}t$, the probability that there exists a sequence of successive clock rings between $3\bar{v}t - y$ and $\max_{u \in [0,t]} |X(\sigma_u)|$ is less than $O(e^{-t})$. On the event where there is no such sequence, $\mathbb{1}_{X(\sigma_t)=-y}$ and $f(\theta_{3\bar{v}t-y}\sigma_t)$ are independent. Therefore,

$$\mathbb{E}_\sigma [f(\theta_{X(\sigma_t)+3\bar{v}t}\sigma_t)] = \sum_{y=\underline{v}t}^{\bar{v}t} \mathbb{P}_\sigma(X(\sigma_t) = -y) \mathbb{E}_\sigma [f(\theta_{3\bar{v}t-y}\sigma_t)] + O(e^{-\gamma t} + e^{-t}). \quad (5.1)$$

In order to apply our relaxation result Corollary 3.3 on the interval

$$[3\bar{v}t - y, 3\bar{v}t - y + M],$$

we need to check that

$$\begin{aligned} 3\bar{v}t - y - \bar{v}t &\geq \underline{v}t \\ 3\bar{v}t - y + M + \bar{v}t &\leq M + (4\bar{v} - \underline{v})t, \end{aligned}$$

which is clearly satisfied if $y \in [\underline{v}t, \bar{v}t]$. Therefore, our assumption on σ and Corollary 3.3 imply that

$$|\mathbb{E}_\sigma [f(\theta_{3\bar{v}t-y}\sigma_t)]| \leq Ce^{-c\sqrt{t}},$$

which in turn yields the desired result. □

6 Invariant measure: proof of Theorem 2.1

Proof of Theorem 2.1. We start with two initial configurations σ and σ' in LO_0 and we prove that there exist $d^* > 0, c > 0$ (independent of (σ, σ')) such that for t large enough

$$\|\tilde{\mu}_t^\sigma - \tilde{\mu}_t^{\sigma'}\|_{[0,d^*t]} \leq e^{-ce^{(\log t)^{1/4}}}, \quad (6.1)$$

where $\tilde{\mu}_t^\sigma$ is the distribution of the configuration seen from the front at time t , that is $\theta_{X(\sigma_t)}\sigma_t$.

Thanks to Theorem 5.1 we know that far from the front the configurations starting respectively from σ and σ' will be close to a configuration sampled by the equilibrium measure, so they will be close to one another (for the total variation distance). Following the strategy of [Blo13, GLM15], we construct a coupling where we use this property and where we wait until the configurations also coincide near to the front. Given $\epsilon > 0$ and $t > 0$, we fix the following quantities:

$$\begin{aligned} t_0 &= (1 - \epsilon)t \\ \Delta_1 &= e^{(\log t)^{1/4}} \\ \Delta_2 &= (\log t)^{3/4} \\ \Delta &= \Delta_1 + \Delta_2. \end{aligned}$$

The ‘perfect procedure’ would be:

- Step 0. Both configurations have a lot of zeros at time t_0
- Step 1. Thanks to these zeros, they both closely match equilibrium far from the front after a time-lag Δ_1 . Thus, they match each other for the same conditions.
- Step 2. Then, during a time-lag Δ_2 , a very favorable event happens and the configurations coincide also near to the front.

Roughly speaking, the steps 0 and 1 are very likely and the step 2 has very small probability. So we will repeat step 2 a lot in order to make it succeed. In practice we also need to repeat step 1 because multiple tries of step 2 could destroy the assets of step 1. To do that, the time $t - t_0$ will be split in $N = \lfloor \frac{\epsilon t}{\Delta} \rfloor$ repetitions of steps 1 and 2, respectively of duration Δ_1 and Δ_2 . For $n \in \{0, \dots, N\}$, let $t_n = t_0 + n\Delta$ (resp. $s_{n+1} = t_n + \Delta_1$) the instants at which each of the N repetitions of step 1 (resp. step 2) begins. The repetition of the N steps is illustrated by Figure 4 and the steps 1 and 2 are illustrated by Figure 5.

During the description of the precise procedure, we will use the basic coupling which consists in making the two configurations evolve according to the graphical representation using the same Poisson clocks and coin tosses (as we did in Section 2.4 between the FA-1f and contact processes). Note that whenever we use the basic coupling in our construction, we mean the basic coupling between two FA-1f processes with generator given by (2.1) (and not to processes “seen from the front”). We will also use a trickier coupling: the Λ -maximal coupling, denoted by $MC_\Lambda(\mu, \mu')$ where (μ, μ') are two probability measures on Ω and Λ is a finite box of \mathbb{Z} . It is defined as follows:

1. we sample $(\sigma, \sigma')_{|\Lambda \times \Lambda}$ according to the maximal coupling (which achieves the total variation distance see e.g. [LPW09]) of the marginals of μ and μ' on Ω_Λ ;
2. we sample $\sigma_{|\mathbb{Z} \setminus \Lambda}$ and $\sigma'_{|\mathbb{Z} \setminus \Lambda}$ independently according to their respective conditional distribution $\mu(\cdot | \sigma_{|\Lambda})$ and $\mu'(\cdot | \sigma'_{|\Lambda})$.

We are now ready to recursively define a coupling $\mathcal{P}^{(n)}$ for $(\tilde{\mu}_{t_n}^\sigma, \tilde{\mu}_{t_n}^{\sigma'})$, with $n \in \{0, \dots, N\}$, that is, a coupling $(\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n})$ between the configurations *seen from the fronts* at time t_n (i.e. $\tilde{\sigma}_{t_n} \sim \theta_{X(\sigma_{t_n})}\sigma_{t_n}$ and $\tilde{\sigma}'_{t_n} \sim \theta_{X(\sigma'_{t_n})}\sigma'_{t_n}$).

- **(Step 0)** $\mathcal{P}^{(0)}$ is the trivial product coupling: to sample $(\tilde{\sigma}_{t_0}, \tilde{\sigma}'_{t_0})$ we run the FA-1f dynamics starting from (σ, σ') according to the product coupling and we take the configurations seen from the fronts at time t_0 .
- $\mathcal{P}^{(n)} \rightarrow \mathcal{P}^{(n+1)}$: we sample $(\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n})$ according to $\mathcal{P}^{(n)}$:
 1. If the configurations coincide on the interval $I_n = [1, d_n]$, where $d_n = 2\underline{v}t_n - (\bar{v} + \underline{v})\Delta n$, then we let them evolve according to the basic coupling during a time lag Δ : we obtain $(\tilde{\sigma}_{t_{n+1}}, \tilde{\sigma}'_{t_{n+1}})$ by running the basic coupling started from $(\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n})$ for a time Δ , and then taking the configurations obtained as seen from the front. Using the basic coupling ensures that the equality of the configurations seen from the front is preserved w.h.p. on the interval $I_{n+1} = [0, d_{n+1}]$. By contrast, beyond distance $d_n - (\bar{v} - \underline{v})\Delta$ from the front, the information from beyond I_n could have propagated, so we can not ensure equality. See Figure 6.
 2. If they do not coincide, we proceed in two steps. **(Step 1)** We first choose $(\tilde{\sigma}_{s_{n+1}}, \tilde{\sigma}'_{s_{n+1}})$ using the Λ_n -maximal coupling between the laws of the configurations *seen from the front* after a time Δ_1 starting from $\tilde{\sigma}_{t_n}$ and $\tilde{\sigma}'_{t_n}$, with $\Lambda_n := [3\bar{v}\Delta_1, 2\underline{v}s_{n+1} - (\bar{v} + \underline{v})\Delta_1]$.

FA-1f front evolution

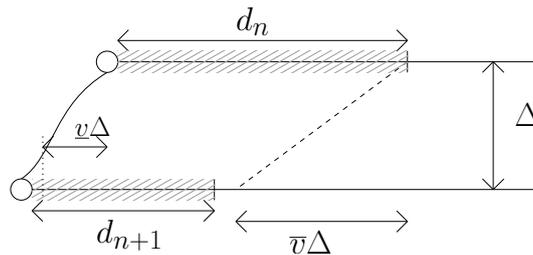

Figure 6: With high probability, equality between two configurations in LO_0 in the dashed interval at initial time results in equality in the dashed interval after time Δ . Indeed, discrepancies coming from the right travel at most at speed \bar{v} , and the front(s) move at least at speed \underline{v} .

- (a) If $\tilde{\sigma}_{s_{n+1}}$ and $\tilde{\sigma}'_{s_{n+1}}$ are not equal in the interval Λ_n , then we let them evolve for a time Δ_2 via the basic coupling.
- (b) **(Step 2)** If instead they agree on Λ_n , then we search for the leftmost common zero of $\tilde{\sigma}_{s_{n+1}}$ and $\tilde{\sigma}'_{s_{n+1}}$ in Λ_n and call x^* its position. If there is no such zero, we define x^* as the right boundary of Λ_n . Then we sample an independent Bernoulli random variable β with $\mathbb{P}(\beta = 1) = e^{-2\Delta_2}$. The event $\{\beta = 1\}$ corresponds to the fact that the two Poisson clocks associated with x^* and with the origin in the graphical construction do not ring during step 2. Using $(\tilde{\sigma}_{s_{n+1}}, \tilde{\sigma}'_{s_{n+1}})$ as initial configurations, we sample two new configurations as follows.
 - i. If $\beta = 1$ then we fix the configurations at x^* as $\tilde{\sigma}_{s_{n+1}}(x^*), \tilde{\sigma}'_{s_{n+1}}(x^*)$. On $[1, x^* - 1]$, we sample the two configurations using the maximal coupling for the FA-1f process run during time Δ_2 , with boundary conditions at x^* being $\tilde{\sigma}_{s_{n+1}}(x^*)$ and $\tilde{\sigma}'_{s_{n+1}}(x^*)$ respectively, and 0 at the origin. Finally, we sample the configurations on the right of x^* and on the left of the origin using the basic coupling during time Δ_2 with the same boundary conditions. Let ξ_{n+1} be the (common) increment of the front during that time. See Figure 5.
 - ii. If $\beta = 0$ then we let evolve $(\tilde{\sigma}_{s_{n+1}}, \tilde{\sigma}'_{s_{n+1}})$ for a time Δ_2 via the basic coupling conditioned to have at least one ring either at x^* or at the origin (or both).

Once procedure (a) or (b) is completed, we define $(\tilde{\sigma}_{t_{n+1}}, \tilde{\sigma}'_{t_{n+1}})$ as the version seen from their fronts of the configurations we obtained.

The final coupling $\mathcal{P}_{\sigma, \sigma'}^t$ is obtained by sampling $(\tilde{\sigma}_{t_N}, \tilde{\sigma}'_{t_N})$ according to $\mathcal{P}^{(N)}$, then applying the basic coupling during a time $t - t_N$ and then defining $(\tilde{\sigma}_t, \tilde{\sigma}'_t)$ as the configurations seen from the fronts at that time.

In the following, \mathcal{P} denotes the joint distribution of all the variables used to define the coupling above. It will also be useful to introduce the following notation: for $A \subset LO_0 \times LO_0$ measurable, $n = 1, \dots, N$, if $\mathcal{A}_n = \{(\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n}) \in A\}$, we write

$$\mathcal{P}_{\mathcal{A}_n}(\cdot) := \sup_{(\eta, \eta') \in A} \mathcal{P}(\cdot \mid (\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n}) = (\eta, \eta'))$$

and

$$\mathcal{P}_{\mathcal{A}_n, \beta=1}(\cdot) := \sup_{(\eta, \eta') \in A} \mathcal{P}(\cdot \mid (\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n}) = (\eta, \eta'), \beta = 1).$$

We define these quantities similarly if $\mathcal{A}_n = \{(\tilde{\sigma}_{s_n}, \tilde{\sigma}'_{s_n}) \in A\}$.

We can now study the probabilities of the events that we expect to see at the step n of the previous procedure.

- At time t_n , we hope for enough zeros, that is, for the occurrence of the event

$$\begin{aligned} \mathcal{Z}_n &= \left\{ \text{no 0-gap greater than } \sqrt{\Delta_1} \text{ on } [\underline{v}\Delta_1, 2\underline{v}t_n] \text{ behind the front at time } t_n \right\} \\ &:= \left\{ \tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n} \in \mathcal{H} \left(\underline{v}\Delta_1, 2\underline{v}t_n, \sqrt{\Delta_1} \right) \right\}. \end{aligned}$$

The distance $\sqrt{\Delta_1}$ is the maximal space that we allow between two zeros to relax to equilibrium at the next step; the distance $2\underline{v}t_n$ is the maximal distance where we can expect zeros without making any hypothesis on the initial configuration. By the first case of Lemma 4.4 we have

$$\mathcal{P}(\mathcal{Z}_n) \geq 1 - 2(2\underline{v}t_n)^2 e^{-c\sqrt{\Delta_1}}. \tag{6.2}$$

- At time s_{n+1} , conditioning on the event \mathcal{Z}_n , we first can relax on the interval seen from the front $\Lambda_n = [3\bar{v}\Delta_1, 2\underline{v}s_{n+1} - (\bar{v} + \underline{v})\Delta_1]$ with error $O(e^{-c'\sqrt{\Delta_1}})$ in term of total variation by Theorem 5.1. Since the distributions of both configurations are close to μ on Λ_n , they are also close to each other, and denoting by $\mathcal{Q}_n = \{\tilde{\sigma}_{s_{n+1}} = \tilde{\sigma}'_{s_{n+1}} \text{ on } \Lambda_n\}$ and sampling the configurations according to the Λ_n -maximal coupling, we have

$$\mathcal{P}_{\mathcal{Z}_n}(\mathcal{Q}_n^c) = O(e^{-c'\sqrt{\Delta_1}}). \tag{6.3}$$

Let \mathcal{B}_n the event corresponding to the fact that x^* is at distance less than $\frac{\sqrt{\Delta_2}}{2}$ from the left boundary of Λ_n , that is

$$\mathcal{B}_n := \left\{ x^* \leq 3\bar{v}\Delta_1 + \frac{\sqrt{\Delta_2}}{2} \right\}.$$

On \mathcal{Q}_n , \mathcal{B}_n is implied by

$$\tilde{\mathcal{B}}_n := \left\{ (\tilde{\sigma}_{s_{n+1}})_{|[3\bar{v}\Delta_1, 3\bar{v}\Delta_1 + \frac{\sqrt{\Delta_2}}{2}] } \neq 1 \right\}.$$

By Theorem 5.1,

$$\mathcal{P}_{\mathcal{Z}_n}(\tilde{\mathcal{B}}_n^c) \leq p^{\frac{\sqrt{\Delta_2}}{2}} + O(e^{-c'\sqrt{\Delta_1}}),$$

and therefore

$$\mathcal{P}_{\mathcal{Z}_n}(\mathcal{B}_n^c \cap \mathcal{Q}_n) \leq p^{\frac{\sqrt{\Delta_2}}{2}} + O(e^{-c'\sqrt{\Delta_1}}), \tag{6.4}$$

Then, we also use the zeros at time t_n to generate zeros between the front and Λ_n at time s_{n+1} . Actually the event \mathcal{Z}_n implies that $\tilde{\sigma}_{t_n}, \tilde{\sigma}'_{t_n} \in \mathcal{H}(0, 3\bar{v}\Delta_1, 2\underline{v}\Delta_1)$ because $\underline{v}\Delta_1 + \sqrt{\Delta_1} \leq 2\underline{v}\Delta_1$. We consider the event

$$\begin{aligned} \mathcal{Z}'_n &= \left\{ \text{no 0-gap greater than } \frac{\sqrt{\Delta_2}}{2} \text{ on } \left[\frac{\sqrt{\Delta_2}}{2}, 3\bar{v}\Delta_1 \right] \text{ behind the front at time } s_{n+1} \right\} \\ &:= \left\{ \tilde{\sigma}_{s_{n+1}}, \tilde{\sigma}'_{s_{n+1}} \in \mathcal{H} \left(\frac{\sqrt{\Delta_2}}{2}, 3\bar{v}\Delta_1, \frac{\sqrt{\Delta_2}}{2} \right) \right\}. \end{aligned}$$

Applying the second case of Lemma 4.4 we have that:

$$\mathcal{P}_{\mathcal{Z}_n}(\mathcal{Z}'_n{}^c) \leq \frac{4\Delta_1^2}{\sqrt{\Delta_2}} e^{-c\frac{\sqrt{\Delta_2}}{2}} + 6\bar{v}\Delta_1^2 e^{-c(\Delta_1 \wedge \frac{\sqrt{\Delta_2}}{2})} = O(e^{-c'\sqrt{\Delta_2}}). \tag{6.5}$$

- At time t_{n+1} conditioning on the events $\mathcal{Z}'_n, \mathcal{Q}_n, \mathcal{B}_n$ and on the fixation of the zeros on $X(s_{n+1})$ and x^* (i.e. $\beta = 1$), we can relax to equilibrium on $[X(s_{n+1}) + 1, X(s_{n+1}) + x^* - 1]$, that is, on the interval $[1 - \xi_{n+1}, x^* - 1 - \xi_{n+1}]$ seen from the front. So we have for all $y \in \Lambda_n$ at distance less than $\frac{\sqrt{\Delta_2}}{2}$ from the left boundary of Λ_n :

$$\mathcal{P}_{\mathcal{Z}'_n, \mathcal{Q}_n, \mathcal{B}_n, x^*=y, \beta=1} \left(\tilde{\sigma}_{t_{n+1}} \neq \tilde{\sigma}'_{t_{n+1}} \text{ on } [1 - \xi_{n+1}, x^* - 1 - \xi_{n+1}] \mid \right) = O(e^{-c'\sqrt{\Delta_2}}), \tag{6.6}$$

applying (3.4). Furthermore, if the configurations coincide on Λ_n at time s_{n+1} , then we can control the probability that they coincide on $\Lambda_n - \xi_{n+1}$ minus a sub interval of size $\bar{v}\Delta_2$ at time t_{n+1} by the probability of the event $F(d_n, d_n - \bar{v}\Delta_2, \Delta_2)$ corresponding to the propagation of the information located beyond Λ_n . Indeed, by Lemma 2.6 and Corollary 4.2, we have (recall Figure 6),

$$\begin{aligned} \mathcal{P}_{\mathcal{Q}_n, \beta=1} \left(\tilde{\sigma}_{t_{n+1}} \neq \tilde{\sigma}'_{t_{n+1}} \text{ on } [x^* + 1 - \xi_{n+1}, d_{n+1}] \right) &\leq \mathbb{P}(F(d_n, d_n - \bar{v}\Delta_2, \Delta_2)) \\ &+ \mathcal{P}(\xi_{n+1} \geq -\underline{v}\Delta_2) = O(e^{-c'\Delta_2}), \end{aligned} \tag{6.7}$$

where the first inequality comes from the fact that, if $\xi_n \leq -\underline{v}\Delta_2$, $d_n - \bar{v}\Delta_2 - \xi_{n+1} \geq d_{n+1}$. To conclude, notice that by construction

$$\mathcal{P} \left(\tilde{\sigma}_{t_{n+1}} \neq \tilde{\sigma}'_{t_{n+1}} \text{ on } [1, -\xi_{n+1}] \mid \beta = 1 \right) = 0. \tag{6.8}$$

Combining (6.6), (6.7) and (6.8), we get

$$\mathcal{P}_{\mathcal{Z}'_n, \mathcal{Q}_n, \mathcal{B}_n, \beta=1} \left(\tilde{\sigma}_{t_{n+1}} \neq \tilde{\sigma}'_{t_{n+1}} \text{ on } [1, d_{n+1}] \right) = O(e^{-c'\sqrt{\Delta_2}}). \tag{6.9}$$

Let \mathcal{M}_n be the event of matching in $I_n = [1, d_n]$ at time t_n :

$$\mathcal{M}_n^c = \{ \tilde{\sigma}_{t_n} \neq \tilde{\sigma}'_{t_n} \text{ on } I_n \},$$

and denote by p_n the probability that the coupling $\mathcal{P}^{(n)}$ is not successful, that is, $p_n = \mathcal{P}(\mathcal{M}_n^c)$. With the previous estimates in mind, we prove the following recursive relation:

$$p_{n+1} \leq Ce^{-c\Delta_1} + p_n \left(1 - \frac{1}{2}e^{-2\Delta_2} \right). \tag{6.10}$$

Indeed, using the previously introduced event \mathcal{Z}_n , we have that

$$\begin{aligned} \mathcal{P}(\mathcal{M}_{n+1}^c) &\leq \mathcal{P}(\mathcal{M}_{n+1}^c \cap \mathcal{M}_n^c \cap \mathcal{Z}_n) + \mathcal{P}(\mathcal{Z}_n^c) + \mathcal{P}(\mathcal{M}_{n+1}^c \cap \mathcal{M}_n) \\ &\leq \mathcal{P}(\mathcal{M}_{n+1}^c \mid \mathcal{M}_n^c \cap \mathcal{Z}_n) \mathcal{P}(\mathcal{M}_n^c) + \mathcal{P}(\mathcal{Z}_n^c) \\ &\quad + \mathbb{P}(F(d_n, d_n - \bar{v}\Delta, \Delta)) + \sup_{\omega \in LO_0} \mathbb{P}_\omega(X(\omega_\Delta) > -\underline{v}\Delta). \end{aligned} \tag{6.11}$$

The last two terms come from a reasoning similar to what we did in (6.7). By Lemma 2.6 and Corollary 4.2, their contribution is $O(e^{-c\Delta})$. The quantity $\mathcal{P}(\mathcal{Z}_n^c)$ has been controlled in (6.2) so we now have to study $\mathcal{P}(\mathcal{M}_{n+1}^c \mid \mathcal{M}_n^c \cap \mathcal{Z}_n)$. Now we condition by the favorable events at time s_{n+1} :

$$\begin{aligned} \mathcal{P}(\mathcal{M}_{n+1}^c \mid \mathcal{Z}_n \cap \mathcal{M}_n^c) &\leq \mathcal{P}_{\mathcal{Z}_n \cap \mathcal{M}_n^c}(\mathcal{M}_{n+1}^c \mid \mathcal{Z}'_n \cap \mathcal{Q}_n \cap \mathcal{B}_n) \\ &\quad + \mathcal{P}_{\mathcal{Z}_n}(\mathcal{Z}_n^{c'}) + \mathcal{P}_{\mathcal{Z}_n}(\mathcal{Q}_n^c) + \mathcal{P}_{\mathcal{Z}_n}(\mathcal{B}_n^c \cap \mathcal{Q}_n). \end{aligned}$$

The last terms have been controlled by (6.3), (6.4) and (6.5).

Finally, using (6.9)

$$\begin{aligned} & \mathcal{P}(\mathcal{M}_{n+1}^c \mid \mathcal{Z}'_n \cap \mathcal{Q}_n \cap \mathcal{B}_n \cap \mathcal{Z}_n \cap \mathcal{M}_n^c) \\ & \leq 1 - \mathbb{P}(\beta = 1) (1 - \mathcal{P}(\mathcal{M}_{n+1}^c \mid \{\beta = 1\} \cap \mathcal{Z}'_n \cap \mathcal{Q}_n \cap \mathcal{B}_n \cap \mathcal{Z}_n \cap \mathcal{M}_n^c)) \\ & \leq 1 - e^{-2\Delta_2} \frac{1}{2}, \end{aligned}$$

for t large enough. Combining with (6.11) we obtain the desired recursivity (6.10). So, we get

$$p_N \leq \left(1 - \frac{1}{2}e^{-2\Delta_2}\right)^N + Ce^{-c\Delta_1}e^{\Delta_2}$$

and we conclude that $p_N = O(e^{-ce^{(\log t)^{1/4}}})$, replacing Δ_1, Δ_2, N by their chosen values.

To conclude the proof of (6.1), we now compute the distance on which the matching occurs w.h.p. At time t_N the coupling was successful on I_N with probability $1 - p_N$. Note that $d_N \geq (2\underline{v} - \epsilon(\bar{v} + \underline{v}))t - 2\underline{v}\Delta$. Let $\epsilon = \frac{\underline{v}}{2(\bar{v} + \underline{v})}$ and $d^* = \underline{v}$. Then $d^*t \leq d_N$ and if we let the configurations evolve according to the basic coupling between time t_N and time t we have

$$\mathcal{P}(\tilde{\sigma}_t \neq \tilde{\sigma}'_t \text{ on } [0, d^*t]) \leq p_N + \mathbb{P}(F(d_N, d^*t, t - t_N)) + \sup_{\omega \in LO_0} \mathbb{P}(X(\omega_{t-t_N}) \geq 0).$$

Since $d_N - d^*t \geq \underline{v}t/2 - 2\underline{v}\Delta \geq \bar{v}\Delta \geq \bar{v}(t - t_N)$, we have that $\mathbb{P}(F(d_N, d^*t, t - t_N)) \leq e^{-ct}$ and we obtained the announced convergence.

The fact that the set of probability measures on Ω is compact gives us the existence of invariant measures. The uniqueness and convergence starting from any π measure on LO_0 comes from (6.1) and we conclude the proof of Theorem 2.1. \square

7 Limit Theorems

7.1 Moments and covariances

Thanks to Theorem 2.1 we can study the increments of the front. We consider $\sigma \in LO_0$. For $n \in \mathbb{N}$, we introduce the following increments

$$\xi_n = X(\sigma_n) - X(\sigma_{n-1}),$$

so that, for $t > 0$,

$$X(\sigma_t) = \sum_{n=1}^{\lfloor t \rfloor} \xi_n + X(\sigma_t) - X(\sigma_{\lfloor t \rfloor}).$$

In order to prove a law of large numbers and a central limit theorem, we want to control the moments (Lemma 7.1) and the covariances (Lemma 7.4) of these front increments. Lemma 7.3 proves the convergence of $\mathbb{E}_\sigma[\xi_n]$ to $\mathbb{E}_\nu[\xi_1]$, which leads to the fact that the covariance between ξ_j and ξ_n decays fast enough.

Lemma 7.1. For $f : \mathbb{N} \rightarrow \mathbb{R}$ such that $e^{-|x|}f(x)^2 \in L^1$ we have

$$\sup_{\sigma \in LO_0} \mathbb{E}_\sigma [f(\xi_1)^2] = c(f) < \infty. \tag{7.1}$$

Remark 7.2. Consequently, we have the same result for $\mathbb{E}_\sigma[f(\xi_n)^2]$, for the expectation under ν and for the covariances between increments.

Proof. The result follows from the finite speed of propagation. Indeed, by Lemma 2.6 we have that, for $\sigma \in LO_0$ and $|x| \geq \bar{v}$

$$\mathbb{P}_\sigma(\xi_1 = x) \leq \mathbb{P}(F(0, x, 1)) \leq e^{-|x|}.$$

Then, for every $\sigma \in LO_0$, we have

$$\begin{aligned} \mathbb{E}_\sigma [f(\xi_1)^2] &\leq \max_{|x| \leq \bar{v}} f(x)^2 + \sum_{|x| > \bar{v}} f(x)^2 \mathbb{P}_\sigma(\xi_1 = x) \\ &\leq c(f) < \infty. \end{aligned}$$

The right bound does not depend on σ , so we obtain the announced result. □

Lemma 7.3. *There exists $\gamma > 0$ such that for $f : \mathbb{N} \rightarrow \mathbb{R}$ with $e^{-|x|} f(x)^2 \in L^1$,*

$$\sup_{\sigma \in LO_0} |\mathbb{E}_\sigma [f(\xi_n)] - \mathbb{E}_\nu [f(\xi_1)]| \leq C(f) e^{-\gamma e^{(\log n)^{1/4}}}.$$

Proof. We use the Markov property at time $n - 1$ to write

$$\mathbb{E}_\sigma [f(\xi_n)] = \int d\mu_{n-1}^\sigma(\sigma') \mathbb{E}_{\sigma'} [f(\xi_1)],$$

where μ_t^σ is the distribution of the configuration at time t starting from σ . Let $\Phi_t(\sigma')$ be the configuration equal to $\theta_{X(\sigma')} \sigma'$ on $[0, d^*t]$ and equal to 1 elsewhere (we recall that d^* is a quantity defined in Theorem 2.1). Under the basic coupling (denoted by \mathcal{E} in the following computations), the front of the configuration after a time δ starting with σ' is different from the one starting with $\Phi_t(\sigma')$ only if the event $\tilde{F}(0, d^*t, \delta)$ occurs. So, denoting by X and \tilde{X} the first increments starting respectively from configurations σ' and $\Phi_{n-1}(\sigma')$, we have that

$$\begin{aligned} \mathbb{E}_{\sigma'} [f(\xi_1)] - \mathbb{E}_{\Phi_{n-1}(\sigma')} [f(\xi_1)] &= \mathcal{E} \left[\left(f(X) - f(\tilde{X}) \right) \mathbb{1}_{X \neq \tilde{X}} \right] \\ &\leq \sqrt{\mathcal{E} \left[\left(f(X) - f(\tilde{X}) \right)^2 \right]} \sqrt{\mathcal{E} \left[\mathbb{1}_{X \neq \tilde{X}} \right]} \\ &\leq 2 \sqrt{\sup_{\sigma \in LO_0} \mathbb{E}_\sigma [f(\xi_1)^2]} \sqrt{\mathbb{P}(\tilde{F}(0, d^*(n-1), \delta))}. \end{aligned}$$

Therefore, if $n - 1 \geq \frac{\bar{v}}{d^*}$,

$$\sup_{\sigma \in LO_0} \int d\mu_{n-1}^\sigma(\sigma') \left(\mathbb{E}_{\sigma'} [f(\xi_1)] - \mathbb{E}_{\Phi_{n-1}(\sigma')} [f(\xi_1)] \right) \leq 2e^{-\frac{d^*(n-1)}{2}} \sqrt{\sup_{\sigma \in LO_0} \mathbb{E}_\sigma [f(\xi_1)^2]}.$$

Similarly (taking the expectation w.r.t. ν), we have that

$$\mathbb{E}_\nu [f(\xi_1)] - \int d\nu(\sigma') \mathbb{E}_{\Phi_{n-1}(\sigma')} [f(\xi_1)] \leq 2e^{-\frac{d^*(n-1)}{2}} \sqrt{\sup_{\sigma \in LO_0} \mathbb{E}_\sigma [f(\xi_1)^2]}.$$

Besides, we can write that

$$\begin{aligned} &\left| \int d\mu_{n-1}^\sigma(\sigma') \mathbb{E}_{\Phi_{n-1}(\sigma')} [f(\xi_1)] - \int d\nu(\sigma') \mathbb{E}_{\Phi_{n-1}(\sigma')} [f(\xi_1)] \right| \\ &\leq 2 \sqrt{\sup_{\sigma \in LO_0} \mathbb{E}_\sigma [f(\xi_1)^2]} \sup_{\sigma \in LO_0} \left\| \mu_{n-1}^\sigma - \nu \right\|_{[0, d^*(n-1)]}^{1/2}. \end{aligned}$$

Finally, putting everything together

$$\sup_{\sigma \in LO_0} |\mathbb{E}_\sigma [f(\xi_n)] - \mathbb{E}_\nu [f(\xi_1)]| \leq 2\sqrt{c(f)} \left(4e^{-\frac{d^*(n-1)}{2}} + \sup_{\sigma \in LO_0} \|\mu_{n-1}^\sigma - \nu\|_{[0, d^*(n-1)]}^{1/2} \right).$$

Applying Theorem 2.1 we obtain the desired control. \square

Lemma 7.4. *There exists $\gamma > 0$ such that, for $f : \mathbb{N} \rightarrow \mathbb{R}$, $e^{-|x|} f(x)^2 \in L^1$ and $j < n$ two positive integers,*

1. $\sup_{\sigma \in LO_0} |\text{Cov}_\sigma [f(\xi_j), f(\xi_n)]| \leq C(f) e^{-\gamma e^{(\log(n-j))^{1/4}}}$,

and the same holds for the covariance under ν ;

2. for $j \geq \frac{\bar{v}}{d^*}(n-j)$,

$$\sup_{\sigma \in LO_0} |\text{Cov}_\sigma [f(\xi_j), f(\xi_n)] - \text{Cov}_\nu [f(\xi_1), f(\xi_{n-j+1})]| \leq C(f) e^{-\gamma e^{(\log j)^{1/4}}}.$$

Proof. Let $j < n$ and $\sigma \in LO_0$.

1. The idea is the following one: if the difference between j and n is large enough then ξ_j and ξ_n are almost independent. Let $(\mathcal{F}_j)_{j \in \mathbb{N}}$ be the filtration associated with the random variables $(\xi_j)_{j \in \mathbb{N}}$. Using the Markov property and Cauchy-Schwarz inequality we have that

$$\begin{aligned} |\text{Cov}_\sigma [f(\xi_j), f(\xi_n)]| &= |\text{Cov}_\sigma [f(\xi_j), \mathbb{E}_\sigma [f(\xi_n) | \mathcal{F}_j]]| \\ &= |\text{Cov}_\sigma [f(\xi_j), \mathbb{E}_{\sigma_j} [f(\xi_{n-j})] - \mathbb{E}_\nu [\xi_1]]| \\ &\leq 2\sqrt{\mathbb{E}_\sigma [f(\xi_j)^2]} \sqrt{\mathbb{E}_\sigma \left[(\mathbb{E}_{\sigma_j} [f(\xi_{n-j})] - \mathbb{E}_\nu [\xi_1])^2 \right]}. \end{aligned}$$

Then, we apply Lemma 7.3 and we obtain the first point:

$$\sup_{\sigma \in LO_0} |\text{Cov}_\sigma [f(\xi_j), f(\xi_n)]| = O \left(e^{-\gamma e^{(\log(n-j))^{1/4}}} \right),$$

which is relevant if $n-j$ is large. Combining this with Lemma 7.3 yields the result for the covariance under ν .

2. If $n-j$ is not large but j (and n) are, we are looking at the process after large times so the configurations seen from the front are close to configurations sampled by ν . We can use the same trick as in the proof of the previous lemma, replacing the expectations by the covariances to obtain the second point. Indeed, we have

$$\begin{aligned} &\text{Cov}_\sigma [f(\xi_j), f(\xi_n)] - \text{Cov}_\nu [f(\xi_1), f(\xi_{n-j+1})] \\ &= \mathbb{E}_\sigma [f(\xi_j)f(\xi_n)] - \mathbb{E}_\nu [f(\xi_1)f(\xi_{n-j+1})] \\ &\quad - (\mathbb{E}_\sigma [f(\xi_j)] \mathbb{E}_\sigma [f(\xi_n)] - \mathbb{E}_\nu [f(\xi_1)] \mathbb{E}_\nu [f(\xi_{n-j+1})]). \end{aligned}$$

Using the Markov property at time t_{j-1} , finite speed propagation under the hypothesis $d^*(j-1) \geq \bar{v}(n-j+1)$ and Theorem 2.1, we can show that

$$|\mathbb{E}_\sigma [f(\xi_j)f(\xi_n)] - \mathbb{E}_\nu [f(\xi_1)f(\xi_{n-j+1})]| = O \left(e^{-\gamma e^{(\log j)^{1/4}}} \right).$$

We conclude using Lemma 7.3 which says that

$$\begin{aligned} |\mathbb{E}_\sigma [f(\xi_j)] - \mathbb{E}_\nu [f(\xi_1)]| &= O(e^{-\gamma e^{(\log j)^{1/4}}}) \\ \text{and } |\mathbb{E}_\sigma [f(\xi_n)] - \mathbb{E}_\nu [f(\xi_{n-j+1})]| &= O(e^{-\gamma e^{(\log n)^{1/4}}}). \end{aligned} \quad \square$$

The second point in the previous lemma can be generalized in the following way.

Lemma 7.5. For any $k, n \in \mathbb{N}$ such that $d^*(k - 1) \geq \bar{v}n$ and any bounded function $F : \mathbb{R}^n \rightarrow \mathbb{R}$

$$\sup_{\sigma \in LO_0} |\mathbb{E}_\sigma [F(\xi_k, \dots, \xi_{k+n-1})] - \mathbb{E}_\nu [F(\xi_1, \dots, \xi_n)]| = O\left(\|F\|_\infty e^{-\gamma e^{(\log k)^{1/4}}}\right).$$

Proof. We apply again the method we used for Lemma 7.3. Applying Markov property at time t_{k-1} we have $\mathbb{E}_\sigma [F(\xi_k, \dots, \xi_{k+n-1})] = \int d\mu_{t_{k-1}}^\sigma(\sigma') \mathbb{E}_{\sigma'} [F(\xi_1, \dots, \xi_n)]$. We use the same notation $\Phi_t(\sigma)$ for the configuration equal to $\theta_{X(\sigma)}\sigma$ on $[0, d^*t]$ and equal to 1 elsewhere; then

$$\begin{aligned} & |\mathbb{E}_{\sigma'} [F(\xi_1, \dots, \xi_n)] - \mathbb{E}_{\Phi_{k-1}(\sigma')} [F(\xi_1, \dots, \xi_n)]| \\ & \leq 2 \sqrt{\sup_{\sigma \in LO_0} \mathbb{E}_\sigma [F(\xi_1, \dots, \xi_n)^2]} \sqrt{\mathbb{P}(F(0, d^*(k - 1), n))} \\ & \leq 2\|F\|_\infty e^{-\frac{d^*(k-1)}{2}} \text{ if } d^*(k - 1) \geq \bar{v}n. \end{aligned}$$

Therefore,

$$\begin{aligned} & \left| \int d\mu_{k-1}^\sigma(\sigma') \mathbb{E}_{\Phi_{k-1}(\sigma')} [F(\xi_1, \dots, \xi_n)] - \int d\nu(\sigma') \mathbb{E}_{\Phi_{k-1}(\sigma')} [F(\xi_1, \dots, \xi_n)] \right| \\ & \leq 2\|F\|_\infty \sup_{\sigma \in LO_0} \|\mu_{k-1}^\sigma - \nu\|_{[0, d^*(k-1)]}^{1/2}. \end{aligned}$$

Finally, putting everything together and applying Theorem 2.1, we obtain the announced result. \square

7.2 Law of large numbers and central limit theorem

Proof of Theorem 2.3. We first prove (2.3). We take inspiration from the proof of the law of large numbers of [GK11]. Let $S_n = \sum_{i=1}^n \tilde{\xi}_i$ where $\tilde{\xi}_i = \xi_i - \mathbb{E}_\sigma [\xi_i]$ and $\text{Var}_\sigma [\tilde{\xi}_i] \leq \mathbb{E}_\sigma [\xi_i^2] \leq c$ by Lemma 7.1. First we compute the variance of $\frac{S_n}{n}$:

$$\text{Var}_\sigma \left[\frac{S_n}{n} \right] = \frac{1}{n^2} \sum_{i=1}^n \text{Var}_\sigma [\tilde{\xi}_i] + \frac{2}{n^2} \sum_{j < k} \text{Cov}_\sigma [\tilde{\xi}_j, \tilde{\xi}_k].$$

The first sum is dominated by cn . We control the second one thanks to Lemma 7.4.

$$\begin{aligned} \sum_{k=1}^n \sum_{j=1}^{k-1} \text{Cov}_\sigma [\tilde{\xi}_j, \tilde{\xi}_k] & \leq \sum_{k=1}^n \sum_{j=1}^{k-1} C e^{-\gamma e^{(\log(k-j))^{1/4}}} \\ & \leq n \sum_{j=1}^\infty C e^{-\gamma e^{(\log j)^{1/4}}}. \end{aligned}$$

So, $\text{Var}_\sigma \left[\frac{S_n}{n} \right] \leq \frac{C}{n}$. Applying Chebychev Inequality and Borel-Cantelli Lemma, we deduce that $\frac{S_n}{n}$ converges a.s. To prove the convergence of the complete sequence, we need to control $\text{Var}_\sigma \left[\frac{S_p}{p} - \frac{S_n}{n} \right]$ with $p = p(n) = \lfloor \sqrt{n} \rfloor^2$. It is easy to check that $n - p \leq 2\sqrt{n} \leq p$ for n large enough. We introduce the following quantity

$$D_{n,p} = \tilde{\xi}_{p+1} + \dots + \tilde{\xi}_n.$$

We have that

$$\begin{aligned} \text{Var}_\sigma \left[\frac{S_p}{p} - \frac{S_n}{n} \right] & = \text{Var}_\sigma \left[\left(\frac{1}{p} - \frac{1}{n} \right) S_p - \frac{1}{n} D_{n,p} \right] \\ & = \left(\frac{1}{p} - \frac{1}{n} \right)^2 \text{Var}_\sigma [S_p] + \frac{1}{n^2} \text{Var}_\sigma [D_{n,p}] - 2 \left(\frac{1}{p} - \frac{1}{n} \right) \frac{1}{n} \text{Cov}_\sigma [S_p, D_{n,p}]. \end{aligned}$$

The two first terms are dominated by $\frac{C(n-p)}{n^2} \leq \frac{2C}{n^{3/2}}$. Using the same computations as above, we have that

$$\text{Cov}_\sigma[S_p, D_{n,p}] = \sum_{i=1}^p \sum_{j=p+1}^n \text{Cov}_\sigma[\tilde{\xi}_i, \tilde{\xi}_j] \leq Cp.$$

This yields

$$\text{Var}_\sigma \left[\frac{S_p}{p} - \frac{S_n}{n} \right] \leq \frac{C}{n^{3/2}},$$

and by the same arguments as previously, $\frac{S_{p(n)}}{p(n)} - \frac{S_n}{n}$ converges almost surely to 0, as well as $\frac{S_{p(n)}}{p(n)}$. We deduce that almost surely, $\frac{S_n}{n}$ converges to 0. Moreover, by Lemma 7.3, $\frac{1}{n} \sum_{i=1}^n \mathbb{E}_\sigma[\xi_i]$ is the Cesaro mean of a convergent sequence. It is also clear (e.g. by finite speed of propagation) that $\frac{X(\sigma_t) - \sum_{i=1}^n \xi_i}{t}$ converges a.s. to 0. To identify the limit in (2.3) and conclude, we observe that

$$\frac{d}{dt} \mathbb{E}_\sigma [X(\sigma_t)] = p \cdot \tilde{\mu}_t^\sigma(\tilde{\sigma}(1) = 0) - q,$$

which converges to the announced velocity.

To prove (2.4), we apply Theorem A.1 with $\Phi(k) = \exp(-\exp((\log k)^{1/4}))$, $c^* = \frac{d^*}{v}$ and ν the measure from Theorem 2.1. The required hypotheses were proved in Subsection 7.1. \square

Appendix A A central limit theorem

The following result is a general version of the central limit proved in [GLM15], which was based on a Bolthausen result [Bol82], itself inspired by Stein’s method. It gives a central limit theorem for random variables with some mixing conditions but without stationarity hypotheses.

Theorem A.1. *Let (σ_t) be a Markov process and (\mathcal{F}_t) the adapted filtration. Let $(X_i)_{i \geq 1}$ be real random variables satisfying the following hypotheses:*

1. (a) $\sup_{\sigma} \sup_{n \in \mathbb{N}} \mathbb{E}_\sigma[X_n^2] < \infty$;
 (b) for every $i \geq 1$, X_i is measurable w.r.t. \mathcal{F}_i ;
 (c) for every $k, n \geq 1$, $f : \mathbb{R}^n \rightarrow \mathbb{R}$ measurable such that $\sup_{\sigma} \mathbb{E}_\sigma[f(X_1, \dots, X_n)] < \infty$, for all initial σ , we have the Markov property

$$\mathbb{E}_\sigma[f(X_k, \dots, X_{k+n-1}) \mid \mathcal{F}_{k-1}] = \mathbb{E}_{\sigma_{k-1}}[f(X_1, \dots, X_n)]; \tag{A.1}$$

2. *There exist a decreasing function Φ , constants $C, c^* \geq 1$ and $v \in \mathbb{R}$ and a measure ν such that*

- (a) $\lim_{n \rightarrow \infty} e^{(\log n)^2} \Phi(n) = 0$;
- (b) for every $i \geq 1$, $\mathbb{E}_\nu[X_i] = v$;
- (c) for every k , $f : \mathbb{R} \rightarrow \mathbb{R}$ s.t. $e^{-|x|} f(x) \in L^1(\mathbb{R})$,

$$\sup_{\sigma} |\mathbb{E}_\sigma[f(X_k)] - \mathbb{E}_\nu[f(X_1)]| \leq C\Phi(k); \tag{A.2}$$

- (d) for every k, n such that $k \geq c^* n$,

$$\sup_{\sigma} |\mathbb{E}_\sigma[X_k X_{k+n}] - \mathbb{E}_\nu[X_1 X_{n+1}]| \leq C\Phi(k); \tag{A.3}$$

(e) for every k, n such that $k > c^*n$ and any bounded function $F : \mathbb{R}^n \rightarrow \mathbb{R}$

$$\sup_{\sigma} |\mathbb{E}_{\sigma} [F(X_k, \dots, X_{k+n-1})] - \mathbb{E}_{\nu} [F(X_1, \dots, X_n)]| \leq C \|F\|_{\infty} \Phi(k). \tag{A.4}$$

Then, there exists $s \geq 0$ such that

$$\frac{\sum_{i=1}^n X_i - vn}{\sqrt{n}} \xrightarrow{\mathcal{L}} \mathcal{N}(0, s^2).$$

Lemma A.2. The hypotheses of Theorem A.1 imply that there exists $C' > 0$ such that for every $i \leq j$,

$$\sup_{\sigma} |\text{Cov}_{\sigma}[X_i, X_j]| \leq C' \Phi(j - i), \tag{A.5}$$

$$|\text{Cov}_{\nu}[X_i, X_j]| \leq C' \Phi(j - i), \tag{A.6}$$

$$\sup_{\sigma} |\text{Cov}_{\sigma}[X_i, X_j] - \text{Cov}_{\nu}[X_1, X_{j-i+1}]| \leq C' \Phi(i/c^*) \wedge \Phi(j - i). \tag{A.7}$$

Proof. On the one hand, by Hypothesis (1b) and the Markov property, we have

$$\begin{aligned} \text{Cov}_{\sigma}[X_i, X_j] &= \mathbb{E}_{\sigma} [X_i (\mathbb{E}_{\sigma_i}[X_{j-i}] - \mathbb{E}_{\sigma}[X_j])] \\ &= O(\Phi(j - i)), \end{aligned}$$

where the last equality comes from (A.2) applied twice to $f(x) = x$ and Hypothesis (1a). The same strategy also shows $\text{Cov}_{\nu}[X_1, X_{j-i+1}] = O(\Phi(j - i))$.

On the other hand, if $i \geq c^*(j - i + 1)$, we can apply (A.3) and again (A.2) to get

$$\text{Cov}_{\sigma}[X_i, X_j] = \text{Cov}_{\nu}[X_1, X_{j-i+1}] + O(\Phi(i)). \quad \square$$

Proof of Theorem A.1. We begin by showing that

$$\lim_{n \rightarrow \infty} \frac{1}{n} \text{Var}_{\sigma} \left[\sum_{i=1}^n X_i \right] = \text{Var}_{\nu}[X_1] + 2 \sum_{k=2}^{\infty} \text{Cov}_{\nu}[X_1, X_k] =: s^2 < \infty. \tag{A.8}$$

We have $s^2 < \infty$ by (A.6). Moreover, by (A.2) applied to $f(x) = x^2$,

$$\frac{1}{n} \sum_{i=1}^n \text{Var}_{\sigma}[X_i] = \frac{1}{n} \sum_{i=1}^n (\text{Var}_{\nu}[X_1] + O(\Phi(i))) = \text{Var}_{\nu}[X_1] + O(1/n).$$

Similarly, by (A.7),

$$\begin{aligned} \frac{1}{n} \sum_{i < j \leq n} \text{Cov}_{\sigma}[X_i, X_j] &= \frac{1}{n} \sum_{i < j \leq n} (\text{Cov}_{\nu}[X_1, X_{j-i+1}] + O(\Phi(i/c^*)\Phi(j - i))) \\ &= \sum_{k=2}^{\infty} \text{Cov}_{\nu}[X_1, X_k] + o(1), \end{aligned}$$

which concludes the proof of (A.8).

The proof then depends on the value of s^2 : if $s^2 = 0$, Chebychev's inequality shows that $\frac{\sum_{i=1}^n X_i - vn}{\sqrt{n}} \rightarrow 0$ in probability.

If $s^2 > 0$, the proof appeals to the variation of Stein's method found in [Bol82]. For every i , let $Y_i = X_i - v$. In particular for every i , $\mathbb{E}_{\nu}[Y_i] = 0$. First, we prove the result for random variables Y_i bounded by C_Y and satisfying the hypotheses of the theorem. Let $\ell_n = n^{1/3}$ and

$$S_n = \sum_{k=1}^n Y_k, \quad S_{j,n} = \sum_{k=1}^n \mathbb{1}_{|k-j| \leq \ell_n} Y_k \quad \text{and} \quad \alpha_n = \sum_{j=1}^n \mathbb{E}_{\sigma} [Y_j S_{j,n}].$$

The theorem's hypotheses and the boundedness of the Y_i 's imply that there exists C' such that

1. For every $i \leq j < k \leq l$ we have that

$$\sup_{\sigma} |\text{Cov}_{\sigma} [Y_i Y_j, Y_k Y_l]| \leq C' \Phi(k - j) \text{ if } (k - j) \geq c^*(l - k). \tag{A.9}$$

2. For every $i \leq j \leq k < l$ we have that

$$\sup_{\sigma} |\text{Cov}_{\sigma} [Y_i Y_k, Y_j Y_l]| \leq C' \Phi(l - k), \tag{A.10}$$

$$\sup_{\sigma} |\text{Cov}_{\sigma} [Y_i Y_l, Y_j Y_k]| \leq C' \Phi(l - k). \tag{A.11}$$

We just give details for the first item. We have that

$$\begin{aligned} \text{Cov}_{\sigma} [Y_i Y_j, Y_k Y_l] &= \text{Cov}_{\sigma} [Y_i Y_j, \mathbb{E}_{\sigma_j} [Y_{k-j} Y_{l-j}] - \mathbb{E}_{\nu} [Y_1 Y_{l-k+1}]] \\ &\leq 2C_Y^2 \sup_{\sigma'} |\mathbb{E}_{\sigma'} [Y_{k-j} Y_{l-j}] - \mathbb{E}_{\nu} [Y_1 Y_{l-k+1}]] \end{aligned}$$

and we conclude using hypothesis (A.3). The others cases are obtained applying the Markov property at time k and hypothesis (A.2).

Thanks to (A.5), we have that

$$\begin{aligned} |\text{Var}_{\sigma} [S_n] - \alpha_n| &= \left| \sum_{|i-j| > \ell_n} \text{Cov}_{\sigma} [Y_i, Y_j] - \sum_{|i-j| \leq \ell_n} \mathbb{E}_{\sigma} [Y_i] \mathbb{E}_{\sigma} [Y_j] \right| \\ &= O(n^2 \Phi(\ell_n) + 1) = O(1); \end{aligned}$$

so $\alpha_n = \text{Var}_{\sigma} [S_n](1 + o(1))$ and it is enough to prove that $\frac{S_n}{\sqrt{\alpha_n}}$ is asymptotically normal.

The main idea is to use a lemma from [Bol82], itself inspired from Stein method, which is the following one.

Lemma A.3 (Lemma 2 in [Bol82]). *Let $(\nu_n)_{n \in \mathbb{N}}$ be a sequence of probability measures in \mathbb{R} with*

- (a) $\sup_n \int |x|^2 \nu_n(dx) < \infty$
- (b) $\lim_{n \rightarrow \infty} \int (i\lambda - x) e^{i\lambda x} \nu_n(dx) = 0$ for all $\lambda \in \mathbb{R}$.

Then the sequence (ν_n) converges to the standard normal law.

The proof can be found in [Bol82]. We want to apply this lemma to the distributions of the random variables $\left(\frac{S_n}{\sqrt{\alpha_n}}\right)_{n \in \mathbb{N}}$. By (A.2) applied to $f(x) = x$, the Markov property applied at time k and the boundedness of the Y_i 's, $\mathbb{E}_{\sigma} [Y_k Y_j] = O(\Phi(j - k))$. The verification of item (a) follows.

We now need to check item (b). Let $\lambda \in \mathbb{R}$ and $A_n = \left(i\lambda - \frac{S_n}{\sqrt{\alpha_n}}\right) e^{i\lambda \frac{S_n}{\sqrt{\alpha_n}}}$. To prove that $\mathbb{E}_{\sigma} [A_n]$ goes to 0 we part A_n in three terms:

$$\begin{aligned} A_n^{(1)} &= i\lambda e^{i\lambda \frac{S_n}{\sqrt{\alpha_n}}} \left(1 - \frac{1}{\alpha_n} \sum_{j=1}^n Y_j S_{j,n}\right), \\ A_n^{(2)} &= -\frac{1}{\sqrt{\alpha_n}} e^{i\lambda \frac{S_n}{\sqrt{\alpha_n}}} \sum_{j=1}^n Y_j \left(1 - e^{-i\lambda \frac{S_{j,n}}{\sqrt{\alpha_n}}} - i\lambda \frac{S_{j,n}}{\sqrt{\alpha_n}}\right), \\ A_n^{(3)} &= -\frac{1}{\sqrt{\alpha_n}} \sum_{j=1}^n Y_j e^{i\lambda \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}}}. \end{aligned}$$

The decaying of the two first terms come easily from the estimates on the covariances.

$$\begin{aligned} \mathbb{E}_\sigma \left[\left| A_n^{(1)} \right|^2 \right] &= \lambda^2 \text{Var}_\sigma \left[\frac{1}{\alpha_n} \sum_{j=1}^n Y_j S_{j,n} \right] = \frac{\lambda^2}{\alpha_n^2} \sum_{i,j=1}^n \text{Cov}_\sigma [Y_i S_{i,n}, Y_j S_{j,n}] \\ &= \frac{\lambda^2}{\alpha_n^2} \sum_{i,j=1}^n \sum_{\substack{k:|k-i| \leq \ell_n \\ l:|l-j| \leq \ell_n}} \text{Cov}_\sigma [Y_i Y_k, Y_j Y_l]. \end{aligned}$$

If $|i - j| \geq (c^* + 2)\ell_n$, then w.l.o.g $i \leq k < j \leq l$ and $(j - k) \geq c^*\ell_n \geq c^*(l - j)$; so applying (A.9), we have that

$$\text{Cov}_\sigma [Y_i Y_k, Y_j Y_l] = O(\Phi(j - k)).$$

If we are not in the previous case then w.l.o.g $i \leq k \leq j < l$ and applying (A.10) then

$$|\text{Cov}_\sigma [Y_i Y_k, Y_j Y_l]| = O(\Phi(l - j)).$$

Consequently,

$$\mathbb{E}_\sigma \left[\left| A_n^{(1)} \right|^2 \right] \leq C \frac{\lambda^2}{\alpha_n^2} \left(n^3 \sum_{m=\ell_n}^n \Phi(m) + n\ell_n^2 \sum_{m=0}^{\ell_n} \Phi(m) \right) = o(1).$$

Using the Taylor expansion of the exponential and the fact that $\mathbb{E}_\sigma[S_{j,n}^2] = O(\ell_n)$ thanks to (A.5), we easily control the term $A_n^{(2)}$:

$$\mathbb{E}_\sigma \left[\left| A_n^{(2)} \right| \right] \leq \frac{C\lambda^2}{\sqrt{\alpha_n}} \sum_{j=1}^n \mathbb{E}_\sigma \left[\left| Y_j \right| \cdot \frac{S_{j,n}^2}{\alpha_n} \right] \leq \frac{C\lambda^2}{\sqrt{\alpha_n}} \cdot \frac{C_Y}{\alpha_n} \cdot n \cdot \ell_n = O\left(\frac{\ell_n}{\sqrt{n}}\right) = o(1).$$

To study $\mathbb{E}[A_n^{(3)}]$, Bolthausen uses the stationarity of the field but we do not have this property here. We need to analyse carefully this term as it is done in [GLM15]. First, using the boundedness of the variables (Y_j) and the fact than $\ell_n \ll \sqrt{\alpha_n}$ we just need to prove that

$$\lim_{n \rightarrow \infty} \frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \mathbb{E}_\sigma \left[Y_j e^{i\lambda \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}}} \right] = 0, \forall \lambda \in \mathbb{R}. \tag{A.12}$$

The usefulness of considering the sum from ℓ_n instead of 0 will appear later. We fix M a number (which will eventually depend on n) and we develop the exponential in two parts (its partial sum and its remainder):

$$e^{i\lambda \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}}} = T_{j,n}^M(\lambda) + R_{j,n}^M(\lambda) \text{ with } \begin{cases} T_{j,n}^M(\lambda) = \sum_{m=0}^M \frac{(i\lambda)^m}{m!} \left(\frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right)^m \\ R_{j,n}^M(\lambda) = \sum_{m=M+1}^{\infty} \frac{(i\lambda)^m}{m!} \left(\frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right)^m. \end{cases}$$

Let us first analyse the contribution of $T_{j,n}^M(\lambda)$ to (A.12):

$$\begin{aligned} \frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \mathbb{E}_\sigma [Y_j T_{j,n}^M(\lambda)] &= \frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \sum_{m=0}^M \frac{1}{m!} \left(\frac{i\lambda}{\sqrt{\alpha_n}} \right)^m \mathbb{E}_\sigma \left[Y_j \left(\sum_{\substack{1 \leq i_1 \leq \dots \leq i_m \\ |i_k - j| > \ell_n}} Y_{i_k} \right)^m \right] \\ &= \frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \sum_{m=0}^M \frac{1}{m!} \left(\frac{i\lambda}{\sqrt{\alpha_n}} \right)^m \sum_{i_1, \dots, i_m \in \tau_j^{(m)}} \mathbb{E}_\sigma \left[Y_j \prod_{k=1}^m Y_{i_k} \right] \end{aligned}$$

where $\tau_j^{(m)} = \{(i_1, \dots, i_m) \in \{1, \dots, n\}^m \text{ such that } \forall k, |i_k - j| \geq \ell_n\}$.

Lemma A.4. *If $m \leq \frac{\log n}{7 \log(c^*+1)}$, then for any $j \in \{\ell_n, \dots, n\}$ and any $(i_1, \dots, i_m) \in \tau_j^{(m)}$,*

$$\mathbb{E}_\sigma \left[Y_j \prod_{k=1}^m Y_{i_k} \right] = O(n^{C'_Y} \Phi(\ell_n)),$$

where $C'_Y = \frac{\log C_Y}{7 \log c^*}$.

Proof. Let $m \leq \frac{\log n}{7 \log(c^*+1)}$, $j \in \{\ell_n, \dots, n\}$ and (i_1, \dots, i_m) such that $\forall k, |i_k - j| \geq \ell_n$. We have several cases

1. if $i_m \leq j - \ell_n$, applying Markov property at time i_m and hypothesis (A.2), we have that

$$\left| \mathbb{E}_\sigma \left[Y_j \prod_{k=1}^m Y_{i_k} \right] \right| \leq \mathbb{E}_\sigma \left[\prod_{k=1}^{m-1} |Y_{i_k}| \cdot \left| \mathbb{E}_{\sigma_{i_m}} [Y_{j-i_m}] \right| \right] = O(C_Y^m \Phi(j - i_m)) = O(n^{C'_Y} \Phi(\ell_n)).$$

2. if there exists $b \leq m - 1$ such that $i_b \leq j - \ell_n < j < j + \ell_n \leq i_{b+1}$ then we distinguish two cases:

- (a) If, for all $k \geq b + 2$, $i_k - i_{k-1} \leq (c')^{m-k} \sqrt{\ell_n}$ (with $c' = c^* + 1$) then $c^*(i_m - i_{b+1}) \leq c^*(1 + c' + \dots + (c')^{m-3}) \sqrt{\ell_n} \leq (c')^{m-2} \sqrt{\ell_n} \ll \ell_n \leq i_{b+1} - j$. So, using Markov property at time j and hypothesis (A.4), we have that

$$\begin{aligned} \mathbb{E}_\sigma \left[Y_j \prod_{k=1}^m Y_{i_k} \right] &= \mathbb{E}_\sigma \left[Y_j \prod_{k=1}^b Y_{i_k} \mathbb{E}_{\sigma_{i_j}} [Y_{i_{b+1}-j} \dots Y_{i_m-j}] \right] \\ &= \mathbb{E}_\sigma \left[Y_j \prod_{k=1}^b Y_{i_k} \right] \left(\mathbb{E}_\nu [Y_1 \dots Y_{i_m - i_{b+1}}] \right. \\ &\quad \left. + O \left(C_Y^{m-(b+1)} \Phi(i_{b+1} - j) \right) \right) \\ &= O(n^{C'_Y} \Phi(\ell_n)), \end{aligned}$$

where the last equality comes from the first case where all the indices are smaller than $j - \ell_n$.

- (b) Else, we denote by $k^* = \max\{k \geq b + 1 : i_{k+1} \geq i_k + (c')^{m-k-1} \sqrt{\ell_n}\}$. Then $c^*(i_m - i_{k^*+1}) \leq c^*(1 + c' + \dots + (c')^{m-k^*-2}) \sqrt{\ell_n} \leq (c')^{m-k^*-1} \sqrt{\ell_n} \leq i_{k^*+1} - i_{k^*}$. Applying Markov property at time i_{k^*}

$$\mathbb{E}_\sigma \left[Y_j \prod_{k=1}^m Y_{i_k} \right] = \mathbb{E}_\sigma \left[Y_j \prod_{k=1}^{k^*} Y_{i_k} \right] \left(\mathbb{E}_\nu [Y_1 \dots Y_{i_m - i_{k^*+1}}] + O(C_Y^m \Phi(i_{k^*+1} - i_{k^*})) \right).$$

If all the indices between $b + 1$ and k^* satisfy (2a) then we are reduced to the previous case. If not, we iterate until we are reduced to the previous case or to the first case (all indices smaller than $j - \ell_n$).

3. If $i_1 \geq j + \ell_n$, then we do the same computation as in the previous case with $b = 0$ and we conclude using that $\mathbb{E}_\sigma[Y_j] = O(\Phi(j)) = O(\Phi(\ell_n))$ because $j \geq \ell_n$. \square

We choose $M = \frac{\log n}{7 \log(c^*+1)}$, we use Lemma A.4 and thanks to the hypotheses (2a) on Φ we get that, for every $\lambda \in \mathbb{R}$,

$$\left| \frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \mathbb{E}_\sigma [Y_j T_{j,n}^M(\lambda)] \right| \leq \frac{1}{\sqrt{\alpha_n}} \cdot n \cdot n^{\log n} \cdot O(n^{C'_Y} \Phi(\ell_n)) \cdot e^{\frac{|\lambda|}{\sqrt{\alpha_n}}} = o(1).$$

We now have to understand the contribution of $R_{j,n}^M(\lambda)$ to (A.12). We fix L a number (which will eventually depend on n).

$$R_{j,n}^M(\lambda) = \tilde{R}_{j,n}^M(\lambda) + \bar{R}_{j,n}^M(\lambda) = \sum_{m=M+1}^{\infty} \frac{(i\lambda)^m}{m!} \left(\frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right)^m \mathbb{1}_{\left\{ \left| \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right| \leq L \right\}} + \sum_{m=M+1}^{\infty} \frac{(i\lambda)^m}{m!} \left(\frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right)^m \mathbb{1}_{\left\{ \left| \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right| > L \right\}}.$$

Using classical formulas on the remainder of the exponential series (and Cauchy-Schwarz inequality for the second inequality), we obtain that

$$\frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \mathbb{E}_{\sigma} \left[Y_j \tilde{R}_{j,n}^M(\lambda) \right] \leq \frac{n}{\sqrt{\alpha_n}} \cdot C_Y \cdot \frac{|\lambda|^{M+1} L^{M+1}}{M!} e^{|\lambda|L}, \tag{A.13}$$

$$\frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \mathbb{E}_{\sigma} \left[Y_j \bar{R}_{j,n}^M(\lambda) \right] \leq \frac{n}{\sqrt{\alpha_n}} \cdot C_Y \cdot \max_j \mathbb{E}_{\sigma} \left[e^{2|\lambda| \left| \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right|} \right]^{1/2} \mathbb{P}_{\sigma} \left(\left| \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right| > L \right)^{1/2}. \tag{A.14}$$

The right-hand side of (A.13) will be taken care of by an appropriate choice of L . The right-hand side of (A.14) calls for a better understanding of S_n and $S_{j,n}$.

Lemma A.5. *There exists $c > 0$ such that for any n large enough and any $\beta = O(\sqrt{n}\ell_n^{-1})$,*

$$\mathbb{E}_{\sigma} \left[e^{\beta \frac{|S_n|}{\sqrt{\alpha_n}}} \right] \leq 2e^{c\beta^2}.$$

Proof. For $A \subset \{1, \dots, n\}$, let $Z_A = \sum_{k \in A} Y_k$. It is immediate that $|Z_A| \leq C_Y |A|$.

We partition the interval $\{1, \dots, n\}$ into blocks B of ℓ_n successive integers. Let B be a block such that the smaller index s_B of B is larger than $c^* \ell_n$. Let $t \in \{0, \dots, s_B - c^* \ell_n\}$. We can apply hypothesis (A.4) with the function $F : (x_1, \dots, x_{\ell_n}) \mapsto \exp\left(\frac{\beta \sum x_i \wedge (\ell_n C_Y)}{\sqrt{n}}\right)$ (and the parameter $k = s_B - t > c^* \ell_n$):

$$\begin{aligned} \mathbb{E}_{\sigma} \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \middle| \mathcal{F}_t \right] &= \mathbb{E}_{\sigma_t} \left[\exp \left(\frac{\beta Z_{B-t}}{\sqrt{n}} \right) \right] \\ &= \mathbb{E}_{\nu} \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \right] + O(\|F\|_{\infty} \Phi(s_B - t)) \\ &= \mathbb{E}_{\nu} \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \right] + O(\exp(\beta C_Y \ell_n n^{-1/2}) \Phi(\ell_n)) \end{aligned}$$

where Z_{B-t} designates the sum of ℓ_n variables starting from $s_B - t$. Furthermore, we have that

$$\begin{aligned} \mathbb{E}_{\nu} \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \right] &= \mathbb{E}_{\nu} \left[1 + \frac{\beta Z_B}{\sqrt{n}} + \frac{\beta^2 Z_B^2}{2n} + O \left(\frac{\beta^3 Z_B^3}{n^{3/2}} \right) \right] \\ &= 1 + \frac{\beta^2}{2n} \mathbb{E}_{\nu} [Z_B^2] + O \left(\beta^3 \ell_n n^{-3/2} \mathbb{E}_{\nu} [Z_B^2] \right). \end{aligned}$$

Equation (A.5) tells us that $\mathbb{E}_{\nu}[Z_B^2] = O(\ell_n)$ so

$$\mathbb{E}_{\sigma} \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \middle| \mathcal{F}_t \right] \leq 1 + c \frac{\beta^2 \ell_n}{n}. \tag{A.15}$$

Now we consider \mathcal{B} (and $S_{\mathcal{B}}$ the associate sum) a set of blocks such that the distance between two blocks B and B' of \mathcal{B} is larger than $c^* \ell_n$; in other words, if t_B is the maximal

index in B and $s_{B'}$ is the minimal one in B' then $s_{B'} - t_B > c^* \ell_n$. Let B and B' be two such blocks of \mathcal{B} . Markov property and Equation (A.15) (with $t = t_B$) implies that

$$\begin{aligned} \mathbb{E}_\sigma \left[\exp \left(\beta \frac{Z_B + Z_{B'}}{\sqrt{n}} \right) \right] &= \mathbb{E}_\sigma \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \mathbb{E}_{\sigma_{t_B}} \left[\exp \left(\frac{\beta Z_{B'}}{\sqrt{n}} \right) \mid \mathcal{F}_{t_B} \right] \right] \\ &\leq \mathbb{E}_\sigma \left[\exp \left(\frac{\beta Z_B}{\sqrt{n}} \right) \right] \left(1 + c \frac{\beta^2 \ell_n}{n} \right). \end{aligned}$$

By definition of \mathcal{B} we clearly have that $|\mathcal{B}| \leq \frac{n}{\ell_n}$ so after iteration, we conclude that

$$\mathbb{E}_\sigma \left[\exp \left(\beta \frac{S_{\mathcal{B}}}{\sqrt{n}} \right) \right] \leq \left(1 + c \frac{\beta^2 \ell_n}{n} \right)^{|\mathcal{B}|} \leq \exp \left(\frac{c \beta^2 \ell_n n}{n \ell_n} \right) \leq \exp(c' \beta^2).$$

Let us go back to the whole sum S_n ; we can write $S_n = Z_0 + S_{\mathcal{B}_1} + \dots + S_{\mathcal{B}_{\lceil c^* \rceil}}$ where the \mathcal{B}_i are disjoint sets of blocks with the same property as \mathcal{B} and Z_0 is the sum of the $c^* \ell_n$ first terms. By Hölder's inequality, we have that

$$\mathbb{E}_\sigma \left[\exp \left(\beta \frac{S_n}{\sqrt{n}} \right) \right] \leq \mathbb{E}_\sigma \left[\exp \left(\frac{\beta Z_0}{\sqrt{n}} \right) \right] \prod_{i=1}^{\lceil c^* \rceil} \left(\mathbb{E}_\sigma \left[\exp \left(\beta \frac{S_{\mathcal{B}_i}}{\sqrt{n}} \right)^{\lceil c^* \rceil} \right] \right)^{1/\lceil c^* \rceil} \leq \exp(c'' \beta^2)$$

where we use that $\mathbb{E}_\sigma \left[\exp \left(\frac{\beta Z_0}{\sqrt{n}} \right) \right] \leq 1 + \frac{\beta c_Y \ell_n}{\sqrt{n}}$. We could proceed similarly to control $\mathbb{E}_\sigma \left[\exp \left(-\beta \frac{S_n}{\sqrt{n}} \right) \right]$ and finally $\mathbb{E}_\sigma \left[\exp \left(\beta \frac{|S_n - S_{j,n}|}{\sqrt{n}} \right) \right]$. \square

So, if $L = O(\sqrt{n} \ell_n^{-1})$ then we can apply Lemma A.5 with $\beta = \epsilon L$ (with ϵ small enough) and use the exponential Chebychev inequality to obtain that

$$\mathbb{P}_\sigma \left(\left| \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right| > L \right) \leq e^{-\epsilon L^2} \mathbb{E}_\sigma \left[\exp \left(\beta \left| \frac{S_n - S_{j,n}}{\sqrt{\alpha_n}} \right| \right) \right] \leq e^{-\epsilon' L^2}. \tag{A.16}$$

We recall that we have previously chosen $M = \frac{\log n}{7 \log(c^* + 1)}$. Now we choose

$$L = \frac{\log n}{7 \log(c^* + 1) \cdot (10 \wedge (|\lambda| + 2))}$$

and we use Lemma A.5 and Equation (A.16) in Equation (A.14) to conclude that

$$\lim_{n \rightarrow \infty} \frac{1}{\sqrt{\alpha_n}} \sum_{j=\ell_n}^n \mathbb{E}_\sigma [Y_j R_{j,n}^M(\lambda)] = 0.$$

Putting everything together we conclude the proof for bounded random variables Y_i . We use a classical truncation argument to prove the result for non bounded random variables: let $T^N(x)$ be the truncation operator and $R^N(x)$ the remainder:

$$\begin{aligned} T^N(x) &= \max\{\min\{x, N\}, -N\} \\ R^N(x) &= x - T^N(x). \end{aligned}$$

Thanks to (A.5) we have that

$$\mathbb{E}_\sigma \left[\left(\frac{\sum_{i=1}^n (R^N(Y_i) - \mathbb{E}_\sigma [R^N(Y_i)])}{\sqrt{n}} \right)^2 \right] = \frac{1}{n} \sum_{i,j} \text{Cov}_\sigma [R^N(Y_i), R^N(Y_j)]$$

converges to 0 as N goes to ∞ uniformly in n . Using moreover that $\text{Var}_\sigma [R^N(Y_i)] \rightarrow 0$ as N goes to infity, uniformly in i , we can conclude that the central limit theorem is still valid for the unbounded variables. \square

Appendix B Contact process estimates

In the classical contact process introduced by Harris in [Har74] (with the convention chosen in section 2.2), zeros flip to ones at rate 1 without any constraint, ones flip to zeros at rate $\lambda > 0$ if there is exactly one nearest neighbor zero and at rate 2λ if the two nearest neighbors are zeros. Let (η_t^A) be such a contact process starting from a non empty finite set A of infected particles, that is, the particles in the set A have value 0 and the other ones have value 1. We define $\tau^A = \inf\{t > 0 : \eta_t^A \equiv 1\}$ its extinction time and we denote by $X(\eta_t^A)$ the position of leftmost 0, i.e. the leftmost infected point, at time t .

In [DG83] we can find the following estimates:

Theorem B.1 (Durrett-Griffeath, 1983). *For the contact process with infection rate λ , there exists $\lambda_c \in (0, \infty)$ such that for $\lambda > \lambda_c$ the followings hold. Firstly, there exist C_1 and C_2 such that for A non empty finite set and $t \geq 0$*

$$\mathbb{P}(\tau^A = \infty) > 0 \tag{B.1}$$

$$\mathbb{P}(\tau^A < \infty) \leq C_1 e^{-C_2|A|} \tag{B.2}$$

$$\mathbb{P}(t < \tau^{\{0\}} < \infty) \leq C_1 e^{-C_2 t}. \tag{B.3}$$

Secondly, there exists v_{cp} such that for every $a < v_{cp}$, $t \geq 0$ and $|x| < v_{cp}t$

$$\mathbb{P}(X(\eta_t) > -at | \tau^{\{0\}} = \infty) \leq C_1 e^{-C_2 t} \tag{B.4}$$

$$\mathbb{P}(\eta_t^{\{0\}}(x) \neq \eta_t^{\mathbb{Z}}(x) | \tau^{\{0\}} = \infty) \leq C_1 e^{-C_2 t}. \tag{B.5}$$

From this theorem, we derive the following estimate (used in the proof of Corollary 4.3).

Corollary B.2. *For the threshold contact process defined in paragraph 2.2, if $q > \bar{q} := \frac{2\lambda_c}{1+2\lambda_c}$ the following holds. For every $t > 0$ and $l \in \mathbb{N}$, if I_l is a subset of $[-v_{cp}t, v_{cp}t]$ with size l (where v_{cp} is the constant given by Theorem B.1) then there exist C_3, C_4 such that*

$$\mathbb{P}\left(\forall x \in I_l, \eta_t^{\{0\}}(x) = 1 | \tau^{\{0\}} = \infty\right) \leq C_3 e^{-C_4 t \wedge l}. \tag{B.6}$$

Proof. By obvious monotonicity between threshold contact process and contact process (taking $\lambda = \frac{q}{p}$) it is enough to prove the result for the contact process with parameter $\lambda/2$, which satisfies $\lambda/2 > \lambda_c$. Let $t > 0$, $l \in \mathbb{N}$ and I_l a set of size l . Using duality and (B.2) we can obtain:

$$\mathbb{P}\left(\forall x \in I_l, \eta_t^{\mathbb{Z}}(x) = 1\right) \leq C_1 e^{-C_2 l}. \tag{B.7}$$

If I_l is included in $[-v_{cp}t, v_{cp}t]$ then, using (B.5) and (B.7), we have that

$$\begin{aligned} &\mathbb{P}\left(\forall x \in I_l : \eta_t^{\{0\}}(x) = 1 | \tau^{\{0\}} = \infty\right) \\ &\leq \mathbb{P}\left(\forall x \in I_l : \eta_t^{\mathbb{Z}}(x) = 1 | \tau^{\{0\}} = \infty\right) + \mathbb{P}\left(\exists x \in I_l : \eta_t^{\{0\}}(x) \neq \eta_t^{\mathbb{Z}}(x) | \tau^{\{0\}} = \infty\right) \\ &\leq C_1 e^{-C_2 l} + 2v_{cp}t C_1 e^{-C_2 t} \\ &\leq C_3 e^{-C_4 t \wedge l}. \end{aligned} \tag{B.6}$$
