This paper deals with matrix transformations that preserve the $(p, q)$-convexity of sequences. The main result gives the necessary and sufficient conditions for a nonnegative infinite matrix $A$ to preserve the $(p, q)$-convexity of sequences. Further, we give examples of such matrices for different values of $p$ and $q$.

## 1. Introduction

If $p>0, q>0$, then the sequence $\left\{x_{n}\right\}$ of real numbers is said to be $(p, q)$-convex if

$$
\begin{equation*}
\Delta_{p, q}\left(x_{n}\right)=x_{n}-(p+q) x_{n-1}+p q x_{n-2} \geq 0 \tag{1}
\end{equation*}
$$

for $n \geq 2$. The operator $\Delta_{p, q}$ generates the second-order difference $\Delta^{2}$ when $p=q=1$. Several authors [1-3] have proved various results on the convex sequences defined by $\Delta^{2} x_{n} \geq 0$. Other authors $[4,5]$ have studied the classes of sequences satisfying $\Delta_{1, q}\left(x_{n}\right) \geq 0$. Also, the necessary and sufficient conditions for a sequence to be a $(p, q)$-convex sequence can be found in [6]. Moreover, some inequalities on $(p, q)$-convex sequences are given in $[7,8]$.

In [9-11], the authors discuss the matrix transformations that preserve $(p, q)$-convexity of sequences in the case of a lower triangular matrix with a particular type of matrix transformation. But the question of a general infinite matrix preserving ( $p, q$ )-convexity has not been considered anywhere in the literature. This paper deals with the necessary and sufficient conditions for a nonnegative infinite matrix to preserve $(p, q)$-convexity in both settings when $p \neq q$ and $p=q$.

## 2. Preliminaries

For any given sequence $\left\{x_{n}\right\}$, we can find a corresponding sequence $\left\{c_{k}\right\}$ such that

$$
\begin{align*}
& c_{0}=x_{0} \\
& c_{1}=x_{1}-(p+q) c_{0} \tag{2}
\end{align*}
$$

and, for $k \geq 2$,

$$
\begin{equation*}
c_{k}=x_{k}-\sum_{i=0}^{k-1}\left(p^{k-i}+p^{k-i-1} q+\cdots+p q^{k-i-1}+q^{k-i}\right) c_{i} \tag{3}
\end{equation*}
$$

which implies that $\left\{x_{n}\right\}$ can be represented by

$$
\begin{align*}
& x_{0}=c_{0} \\
& x_{1}=c_{1}+(p+q) c_{0} \tag{4}
\end{align*}
$$

and, for $n \geq 2$,

$$
\begin{align*}
x_{n}= & c_{n}+(p+q) c_{n-1}+\left(p^{2}+p q+q^{2}\right) c_{n-2}+\cdots \\
& +\left(p^{n}+p^{n-1} q+\cdots+p q^{n-1}+q^{n}\right) c_{0}  \tag{5}\\
= & c_{n}+\sum_{i=1}^{n}\left(p^{i}+p^{i-1} q+\cdots+p q^{n-i}+q^{i}\right) c_{n-i} .
\end{align*}
$$

As a consequence, we get the following lemma. A variation of this lemma can be found in [6].

Lemma 1. If the sequence $\left\{x_{n}\right\}$ is given by representation (5), then $\Delta_{p, q}\left(x_{n}\right)=c_{n}$. Thus, the sequence $\left\{x_{n}\right\}$ is $(p, q)$-convex if and only if $c_{n} \geq 0$ for $n \geq 2$.

Proof. It suffices to show that $\Delta_{p, q}\left(x_{n}\right)=x_{n}-(p+q) x_{n-1}+$ $p q x_{n-2}=c_{n}$ for $n \geq 2$. Using (5),

$$
\begin{align*}
& \Delta_{p, q}\left(x_{n}\right)=\left(c_{n}+(p+q) c_{n-1}+\left(p^{2}+p q+q^{2}\right) c_{n-2}\right. \\
& \left.\quad+\cdots+\left(\sum_{0}^{n} p^{n-k} q^{k}\right) c_{0}\right)-(p+q)\left(c_{n-1}\right. \\
& \quad+(p+q) c_{n-2}+\left(p^{2}+p q+q^{2}\right) c_{n-3}+\cdots  \tag{6}\\
& \left.\quad+\left(\sum_{0}^{n-1} p^{n-k-1} q^{k}\right) c_{0}\right)+p q\left(c_{n-2}+(p+q) c_{n-3}\right. \\
& \left.\quad+\left(p^{2}+p q+q^{2}\right) c_{n-4}+\cdots+\left(\sum_{0}^{n-2} p^{n-k-2} q^{k}\right) c_{0}\right)
\end{align*}
$$

On the right side, we see that the coefficient of $c_{n}=1$, and the coefficient of $c_{n-r}=0$ for $r=1,2, \ldots, n$. Thus,

$$
\begin{equation*}
\Delta_{p, q}\left(x_{n}\right)=c_{n} \quad \text { for } n \geq 2 \tag{7}
\end{equation*}
$$

Hence, we have the previous lemma.
Also, in (5), the representation of $x_{n}$ in terms of $c_{n}$ can be written as follows:

$$
\begin{align*}
x_{n} & =c_{n}+\sum_{i=0}^{n-1}\left(p^{n-i}+p^{n-i-1} q+\cdots+q^{n-i}\right) c_{i} \\
& = \begin{cases}c_{n}+\sum_{i=0}^{n-1}\left(\frac{p^{n-i+1}-q^{n-i+1}}{p-q}\right) c_{i}, & \text { if } p \neq q \\
c_{n}+\sum_{i=0}^{n-1}(n-i+1) p^{n-i} c_{i}, & \text { if } p=q\end{cases}  \tag{8}\\
& = \begin{cases}\sum_{i=0}^{n}\left(\frac{p^{n-i+1}-q^{n-i+1}}{p-q}\right) c_{i}, & \text { if } p \neq q \\
\sum_{i=0}^{n}(n-i+1) p^{n-i} c_{i} & \text { if } p=q .\end{cases}
\end{align*}
$$

Now, we give below some definitions. Let $A=\left[a_{n, k}\right]$ be a nonnegative infinite matrix defining a sequence to sequence transformation by

Then, we define the matrices $\left[\alpha_{n, k}\right]$ and $\left[\beta_{n, k}\right]$ as

$$
\begin{align*}
\alpha_{n, k} & =\sum_{j=k}^{\infty} p^{j-k} a_{n, j}=a_{n, k}+p a_{n, k+1}+p^{2} a_{n, k+2}+\cdots \\
\beta_{n, i} & =\sum_{k=i}^{\infty} q^{k-i} \alpha_{n, k}=\alpha_{n, i}+q \alpha_{n, i+1}+q^{2} \alpha_{n, i+2}+\cdots  \tag{10}\\
& =\sum_{k=i}^{\infty} q^{k-i}\left(\sum_{j=k}^{\infty} p^{j-k} a_{n, j}\right)
\end{align*}
$$

Interchanging the order of summation, we get, for each $n=$ $0,1,2, \ldots$, and $i=0,1,2, \ldots$,

$$
\begin{align*}
\beta_{n, i} & =\sum_{j=i}^{\infty}\left(\sum_{k=i}^{j} q^{k-i} p^{j-k}\right) a_{n, j} \\
& =\sum_{j=i}^{\infty}\left(p^{j-i}+q p^{j-i-1}+q^{2} p^{j-i-2}+\cdots+q^{j-i}\right) a_{n, j}  \tag{11}\\
& = \begin{cases}\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-q^{j-i+1}}{p-q}\right) a_{n, j}, & \text { if } p \neq q \\
\sum_{j=i}^{\infty}(j-i+1) p^{j-i} a_{n, j}, & \text { if } p=q .\end{cases}
\end{align*}
$$

Furthermore, for $n \geq 2$,

$$
\begin{align*}
& \Delta_{p, q}\left(\beta_{n, i}\right)=\beta_{n, i}-(p+q) \beta_{n-1, i}+p q \beta_{n-2, i} \\
& \quad= \begin{cases}\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-q^{j-i+1}}{p-q}\right) \Delta_{p, q}\left(a_{n, j}\right), & \text { if } p \neq q \\
\sum_{j=i}^{\infty}(j-i+1) p^{j-i} \Delta_{p, q}\left(a_{n, j}\right), & \text { if } p=q .\end{cases} \tag{12}
\end{align*}
$$

In order for the matrix $\left[\beta_{n, i}\right]$ to be well-defined, we need the matrix $\left[a_{n, k}\right]$ to satisfy certain conditions which will depend on the values of $p$ and $q$.
(I) When $p \neq q$, due to symmetry of $p$ and $q$ in the definition of $\beta_{n, i}$, it is sufficient to consider the following cases:
(a) $0<p, q<1$
(b) $0<p<1, q=1$
(c) $p>1, q=1$
(d) $p>1,0<q<1$
(e) $p, q>1$

Case (a). For $0<p, q<1$, we require the matrix $A$ to satisfy that, for each $n$,

$$
\begin{equation*}
\sum_{k=1}^{\infty} k a_{n, k}<\infty \tag{14}
\end{equation*}
$$

Thus, using (11) and $p, q<1$, we have

$$
\begin{align*}
\beta_{n, i} & =\sum_{j=i}^{\infty}\left(p^{j-i}+q p^{j-i-1}+\cdots+q^{j-i}\right) a_{n, j} \\
& <\sum_{j=i}^{\infty}(j-i+1) a_{n, j}=\sum_{j=i}^{\infty}(j-i) a_{n, j}+\sum_{j=i}^{\infty} a_{n, j}<\infty \tag{15}
\end{align*}
$$

by (14).
Thus, $\beta_{n, i}$ is well-defined.
Case (b). For $0<p<1, q=1$, we require the matrix $A$ to satisfy that, for each $n$,

$$
\begin{equation*}
\sum_{k=0}^{\infty} a_{n, k}<\infty \tag{16}
\end{equation*}
$$

Then using (11), we have

$$
\begin{align*}
\beta_{n, i} & =\sum_{j=i}^{\infty}\left(\frac{1-p^{j-i+1}}{1-p}\right) a_{n, j} \\
& =\frac{1}{1-p}\left((1-p) a_{n, i}+\left(1-p^{2}\right) a_{n, i+1}+\cdots\right)  \tag{17}\\
& <\frac{1}{1-p}\left(a_{n, i}+a_{n, i+1}+\cdots\right), \text { since } 0<p<1 \\
& <\infty \quad \text { by }(16) .
\end{align*}
$$

Thus, $\beta_{n, i}$ is well-defined.
For the cases (c), (d), and (e), we require the matrix $A$ to satisfy that, for each $n$,

$$
\begin{equation*}
\sum_{k=0}^{\infty} p^{k} a_{n, k}<\infty \tag{18}
\end{equation*}
$$

Case (c). When $p>1, q=1$, we have, as in the case (b),

$$
\begin{align*}
\beta_{n, i} & =\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-1}{p-1}\right) a_{n, j} \\
& =\frac{p}{p-1} \sum_{j=i}^{\infty}\left(p^{j-i}-\frac{1}{p}\right) a_{n, j}<\frac{p}{p-1} \sum_{j=i}^{\infty} p^{j-i} a_{n, j}  \tag{19}\\
& \leq \frac{p}{p-1} \sum_{j=i}^{\infty} p^{j} a_{n, j}<\infty \quad \text { by (18). }
\end{align*}
$$

Thus, $\beta_{n, i}$ is well-defined.
Case (d). When $p>1,0<q<1$, from (11),

$$
\begin{equation*}
\beta_{n, i}=\frac{1}{p-q} \sum_{j=i}^{\infty}\left(p^{j-i+1}-q^{j-i+1}\right) a_{n, j} \tag{20}
\end{equation*}
$$

Since $q<p$, using (18), we have $\sum_{j=i}^{\infty} q^{j-i} a_{n, j}<\sum_{j=i}^{\infty} p^{j-i} a_{n, j}<$ $\infty$. Therefore,

$$
\begin{equation*}
\beta_{n, i}=\frac{p}{p-q} \sum_{j=i}^{\infty} p^{j-i} a_{n, j}-\frac{q}{p-q} \sum_{j=i}^{\infty} q^{j-i} a_{n, j}<\infty . \tag{21}
\end{equation*}
$$

Thus $\beta_{n, i}$ is well-defined.
Case (e). When $p, q>1$, we can assume without loss of generality that $p>q$.

Proceeding as in case (d), we see that $\beta_{n, i}$ is well-defined in this case also.
(II) When $p=q$, we consider the following cases:

$$
\begin{align*}
& \text { (f) } 0<p<1 \\
& \text { (g) } p=1  \tag{22}\\
& \text { (h) } p>1 .
\end{align*}
$$

Case $(f)$. For $0<p<1$, we require the matrix $A$ to satisfy that, for each $n$,

$$
\begin{equation*}
\sum_{k=1}^{\infty} k a_{n, k}<\infty \tag{23}
\end{equation*}
$$

Then, using (11), we have

$$
\begin{align*}
\beta_{n, i} & =\sum_{j=i}^{\infty}(j-i+1) p^{j-i} a_{n, j}<\sum_{j=i}^{\infty}(j-i+1) a_{n, j}  \tag{24}\\
& =\sum_{j=i}^{\infty}(j-i) a_{n, j}+\sum_{j=i}^{\infty} a_{n, j}<\infty \quad \text { by }(23) .
\end{align*}
$$

Thus, $\beta_{n, i}$ is well-defined.
Case (g). When $p=1, \Delta_{p, q}$-convexity reduces to the well-known second-order convexity $\Delta^{2}$, which has been investigated in detail in [3].

Case (h). For $p>1$, we require the matrix $A$ to satisfy that, for each $n$,

$$
\begin{equation*}
\sum_{k=1}^{\infty} k p^{k} a_{n, k}<\infty \tag{25}
\end{equation*}
$$

Then, using (11), we have

$$
\begin{align*}
\beta_{n, i} & =\sum_{j=i}^{\infty}(j-i+1) p^{j-i} a_{n, j} \\
& \leq \sum_{j=i}^{\infty}(j-i) p^{j-i} a_{n, j}+\sum_{j=i}^{\infty} p^{j} a_{n, j}<\infty \quad \text { by } \quad(25) . \tag{26}
\end{align*}
$$

Thus, $\beta_{n, i}$ is well-defined.

## 3. Main Results

In this section, we prove the necessary and sufficient conditions for a nonnegative infinite matrix $A$ to transform a $(p, q)$ convex sequence into a $(p, q)$-convex sequence showing that each column of the corresponding matrix $\left[\beta_{n, k}\right]$ is a $(p, q)$ convex sequence.

First, we consider the values of $p$ and $q$, where $p \neq q$ results in the cases listed in (13).

Theorem 2. For $p \neq q$, a nonnegative infinite matrix $A$ satisfying (14), (16), or (18), corresponding to the cases listed in (13), preserves $(p, q)$-convexity of sequences if and only if, for $n=2,3,4, \ldots$,
(i) $\Delta_{p, q}\left(\beta_{n, 0}\right)=0$
(ii) $\Delta_{p, q}\left(\beta_{n, 1}\right)=0$
(iii) $\Delta_{p, q}\left(\beta_{n, i}\right) \geq 0$ for $i \geq 2$
where the matrix $\left[\beta_{n, i}\right]$ is defined by

$$
\begin{equation*}
\beta_{n, i}=\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-q^{j-i+1}}{p-q}\right) a_{n, j} \tag{27}
\end{equation*}
$$

Proof. First, we prove a result on the transformed sequence of any $(p, q)$-convex sequence $\left\{x_{n}\right\}$. Now, we have, from (8),

$$
\begin{equation*}
x_{n}=\sum_{i=0}^{n}\left(\frac{p^{n-i+1}-q^{n-i+1}}{p-q}\right) c_{i}, \tag{28}
\end{equation*}
$$

where $c_{i} \geq 0$ for $i \geq 2$ by Lemma 1 . Then, the $n$th term of the transformed sequence is

$$
\begin{equation*}
(A x)_{n}=\sum_{k=0}^{\infty} a_{n, k} x_{k}=\sum_{k=0}^{\infty} a_{n, k} \sum_{i=0}^{k}\left(\frac{p^{k-i+1}-q^{k-i+1}}{p-q}\right) c_{i} . \tag{29}
\end{equation*}
$$

Interchanging the order of summation,

$$
\begin{align*}
(A x)_{n}= & \sum_{i=0}^{\infty} c_{i} \sum_{k=i}^{\infty} \frac{p^{k-i+1}-q^{k-i+1}}{p-q} a_{n, k} \\
= & c_{0} \sum_{k=0}^{\infty} \frac{p^{k+1}-q^{k+1}}{p-q} a_{n, k}+c_{1} \sum_{k=1}^{\infty} \frac{p^{k}-q^{k}}{p-q} a_{n, k}  \tag{30}\\
& +\sum_{i=2}^{\infty} c_{i} \sum_{k=i}^{\infty} \frac{p^{k-i+1}-q^{k-i+1}}{p-q} a_{n, k} .
\end{align*}
$$

From (11), we have

$$
\begin{equation*}
(A x)_{n}=c_{0} \beta_{n, 0}+c_{1} \beta_{n, 1}+\sum_{i=2}^{\infty} c_{i} \beta_{n, i} \tag{31}
\end{equation*}
$$

Then, for $n \geq 2$,

$$
\begin{align*}
& \Delta_{p, q}(A x)_{n}=(A x)_{n}-(p+q)(A x)_{n-1}+p q(A x)_{n-2} \\
&=\left(c_{0} \beta_{n, 0}+c_{1} \beta_{n, 1}+\sum_{i=2}^{\infty} c_{i} \beta_{n, i}\right) \\
&-(p+q)\left(c_{0} \beta_{n-1,0}+c_{1} \beta_{n-1,1}+\sum_{i=2}^{\infty} c_{i} \beta_{n-1, i}\right) \\
&+p q\left(c_{0} \beta_{n-2,0}+c_{1} \beta_{n-2,1}+\sum_{i=2}^{\infty} c_{i} \beta_{n-2, i}\right)  \tag{32}\\
&= c_{0}\left[\beta_{n, 0}-(p+q) \beta_{n-1,0}+p q \beta_{n-2,0}\right] \\
&+c_{1}\left[\beta_{n, 1}-(p+q) \beta_{n-1,1}+p q \beta_{n-2,1}\right] \\
&+\sum_{i=2}^{\infty} c_{i}\left[\beta_{n, i}-(p+q) \beta_{n-1, i}+p q \beta_{n-2, i}\right] .
\end{align*}
$$

Thus, for any $(p, q)$-convex sequence $\left\{x_{n}\right\}$,

$$
\begin{align*}
\Delta_{p, q}(A x)_{n}= & c_{0} \Delta_{p, q}\left(\beta_{n, 0}\right)+c_{1} \Delta_{p, q}\left(\beta_{n, 1}\right) \\
& +\sum_{i=2}^{\infty} c_{i} \Delta_{p, q}\left(\beta_{n, i}\right) \tag{33}
\end{align*}
$$

Now, to prove the sufficiency of the conditions given in the theorem, assume that (i), (ii), and (iii) are true. Then, by (33),

$$
\begin{equation*}
\Delta_{p, q}(A x)_{n} \geq 0 \tag{34}
\end{equation*}
$$

Thus, the sequence $(A x)_{n}$ is also $(p, q)$-convex.
Conversely, assume that the matrix $A$ preserves ( $p, q$ )convexity of the sequences. Suppose that the condition (i) fails to hold. Then there exists an integer $N \geq 2$ such that

$$
\begin{equation*}
\Delta_{p, q}\left(\beta_{N, 0}\right)=L \neq 0 \tag{35}
\end{equation*}
$$

Consider the following sequence:

$$
\begin{equation*}
u=\left\{-L, \frac{-\left(p^{2}-q^{2}\right)}{p-q} L, \frac{-\left(p^{3}-q^{3}\right)}{p-q} L, \ldots\right\} \tag{36}
\end{equation*}
$$

Then $\left\{u_{n}\right\}$ is a $(p, q)$-convex sequence because, using (2) and Lemma 1,

$$
\begin{align*}
& c_{0}=u_{0}=-L \\
& c_{1}=u_{1}-(p+q) c_{0}=0 \tag{37}
\end{align*}
$$

and, for $i \geq 2$,

$$
\begin{align*}
c_{i}= & \Delta_{p, q}\left(u_{i}\right)=u_{i}-(p+q) u_{i-1}+p q u_{i-2} \\
= & \frac{-\left(p^{i+1}-q^{i+1}\right)}{p-q} L+(p+q) \frac{\left(p^{i}-q^{i}\right)}{p-q} L  \tag{38}\\
& -p q \frac{\left(p^{i-1}-q^{i-1}\right)}{p-q} L=0 .
\end{align*}
$$

Thus, from (33), for the transformed sequence $\left\{(A u)_{n}\right\}$,

$$
\begin{align*}
\Delta_{p, q}(A u)_{N}= & c_{0} \Delta_{p, q}\left(\beta_{N, 0}\right)+c_{1} \Delta_{p, q}\left(\beta_{N, 1}\right) \\
& +\sum_{i=2}^{\infty} c_{i} \Delta_{p, q}\left(\beta_{N, i}\right)=-L^{2}<0, \tag{39}
\end{align*}
$$

which contradicts that the transformed sequence $\left\{(A u)_{n}\right\}$ must be ( $p, q$ )-convex.

Next, suppose that the condition (ii) is not true. This case can be settled by a similar argument by considering the following sequence:

$$
\begin{equation*}
v=\left\{0,-L, \frac{-\left(p^{2}-q^{2}\right)}{p-q} L, \frac{-\left(p^{3}-q^{3}\right)}{p-q} L, \ldots\right\} \tag{40}
\end{equation*}
$$

which implies that

$$
\begin{align*}
& c_{0}=0 \\
& c_{1}=-L  \tag{41}\\
& c_{i}=0 \quad \text { for } i \geq 2 .
\end{align*}
$$

Now, suppose that the condition (iii) is not true. Then there exists an integer $j \geq 2$ such that the $j$ th column-sequence of the matrix $\left[\beta_{n, k}\right]$ is $\operatorname{not}(p, q)$-convex. That is, for some $N \geq 2$,

$$
\begin{equation*}
\Delta_{p, q}\left(\beta_{N, j}\right)=L<0 . \tag{42}
\end{equation*}
$$

Now, consider the following sequence:

$$
\begin{align*}
x=\{ & \left\{0, \ldots, 0,1, \frac{p^{2}-q^{2}}{p-q}, \frac{p^{3}-q^{3}}{p-q}, \ldots\right\} .  \tag{43}\\
& \underset{x_{0}}{\downarrow} \underset{x_{j-1} x_{j}}{\downarrow} \underset{x_{j+1}}{\downarrow},
\end{align*}
$$

Then, $\left\{x_{n}\right\}$ is a $(p, q)$-convex sequence, because, using (2) and Lemma 1, we get

$$
\begin{align*}
c_{i} & =0 \quad \text { for } 0 \leq i \leq j-1 \\
c_{j} & =1 ;  \tag{44}\\
c_{j+1} & =x_{j+1}-(p+q) x_{j}+p q x_{j-1}=0 ;
\end{align*}
$$

and, for $i \geq j+2$,

$$
\begin{equation*}
c_{i}=\Delta_{p, q}\left(x_{i}\right)=0 \quad \text { as in (38). } \tag{45}
\end{equation*}
$$

But, from (33),

$$
\begin{align*}
\Delta_{p, q}(A x)_{N}= & c_{0} \Delta_{p, q}\left(\beta_{N, 0}\right)+c_{1} \Delta_{p, q}\left(\beta_{N, 1}\right) \\
& +\sum_{i=2}^{\infty} c_{i} \Delta_{p, q}\left(\beta_{N, i}\right)=c_{j} \Delta_{p, q}\left(\beta_{N, j}\right)=L \tag{46}
\end{align*}
$$

$$
<0
$$

which again contradicts that $\{A x\}$ is a $(p, q)$-convex sequence. This completes the proof.

Theorem 2 generalizes the necessary and sufficient conditions given in [9, Theorem 2, p. 8] in the case of $p=1$ and $q>0$ with $q \neq 1$.

Next, we consider the values of $p$ and $q$ where $p=q$ results in the cases listed in (22).

Theorem 3. For $p=q$, a nonnegative infinite matrix $A$ satisfying (23) or (25), corresponding to the cases listed in (22), preserves $(p, q)$-convexity of sequences if and only if, for $n=$ 2, 3, 4, ...,
(i) $\Delta_{p, p}\left(\beta_{n, 0}\right)=0$
(ii) $\Delta_{p, p}\left(\beta_{n, 1}\right)=0$
(iii) $\Delta_{p, p}\left(\beta_{n, i}\right) \geq 0$ for $i=2,3, \ldots$,
where the matrix $\left[\beta_{n, i}\right]$ is defined by

$$
\begin{equation*}
\beta_{n, i}=\sum_{j=i}^{\infty}(j-i+1) p^{j-i} a_{n, j} . \tag{47}
\end{equation*}
$$

Proof. First we prove a result on the transformed sequence of any ( $p, p$ )-convex sequence $\left\{x_{n}\right\}$. Now, we have, from (8),

$$
\begin{equation*}
x_{n}=\sum_{i=0}^{n}(n-i+1) p^{n-i} c_{i}, \tag{48}
\end{equation*}
$$

where $c_{i} \geq 0$ for $i \geq 2$ by Lemma 1 . Then, the $n$th term of the transformed sequence is

$$
\begin{equation*}
(A x)_{n}=\sum_{k=0}^{\infty} a_{n, k} x_{k}=\sum_{k=0}^{\infty} a_{n, k}\left(\sum_{i=0}^{k}(k-i+1) p^{k-i} c_{i}\right) . \tag{49}
\end{equation*}
$$

Interchanging the order of summation,

$$
\begin{align*}
(A x)_{n}= & \sum_{i=0}^{\infty} c_{i} \sum_{k=i}^{\infty}(k-i+1) p^{k-i} a_{n, k} \\
= & c_{0} \sum_{k=0}^{\infty}(k+1) p^{k} a_{n, k}+c_{1} \sum_{k=1}^{\infty} k p^{k-1} a_{n, k}  \tag{50}\\
& +\sum_{i=2}^{\infty} c_{i} \sum_{k=i}^{\infty}(k-i+1) p^{k-i} a_{n, k} .
\end{align*}
$$

From (11), we have

$$
\begin{equation*}
(A x)_{n}=c_{0} \beta_{n, 0}+c_{1} \beta_{n, 1}+\sum_{i=2}^{\infty} c_{i} \beta_{n, i} . \tag{51}
\end{equation*}
$$

Then, for $n \geq 2$,

$$
\begin{align*}
& \Delta_{p, p}(A x)_{n}=(A x)_{n}-2 p(A x)_{n-1}+p^{2}(A x)_{n-2} \\
& =\left(c_{0} \beta_{n, 0}+c_{1} \beta_{n, 1}+\sum_{i=2}^{\infty} c_{i} \beta_{n, i}\right) \\
& \quad-2 p\left(c_{0} \beta_{n-1,0}+c_{1} \beta_{n-1,1}+\sum_{i=2}^{\infty} c_{i} \beta_{n-1, i}\right)  \tag{52}\\
& \quad+p^{2}\left(c_{0} \beta_{n-2,0}+c_{1} \beta_{n-2,1}+\sum_{i=2}^{\infty} c_{i} \beta_{n-2, i}\right) .
\end{align*}
$$

Thus, for any $(p, p)$-convex sequence $\left\{x_{n}\right\}$,

$$
\begin{align*}
\Delta_{p, p}(A x)_{n}= & c_{0} \Delta_{p, p}\left(\beta_{n, 0}\right)+c_{1} \Delta_{p, p}\left(\beta_{n, 1}\right) \\
& +\sum_{i=2}^{\infty} c_{i} \Delta_{p, p}\left(\beta_{n, i}\right) \tag{53}
\end{align*}
$$

Now, to prove the sufficiency of the conditions given in the theorem, assume that (i), (ii), and (iii) are true. Then by (53),

$$
\begin{equation*}
\Delta_{p, p}(A x)_{n} \geq 0 \tag{54}
\end{equation*}
$$

Thus, the sequence $(A x)_{n}$ is also $(p, p)$-convex.
Conversely, assume that the matrix $A$ preserves ( $p, p$ )convexity of sequences.

Suppose that the condition (i) fails to hold. Then there exists an integer $N \geq 2$ such that

$$
\begin{equation*}
\Delta_{p, p}\left(\beta_{N, 0}\right)=L \neq 0 . \tag{55}
\end{equation*}
$$

Consider the following sequence:

$$
\begin{equation*}
u=\left\{-L,-2 p L,-3 p^{2} L, \ldots\right\} . \tag{56}
\end{equation*}
$$

It is easy to see, using (2) and Lemma 1 , that $u$ is a $(p, p)$ convex sequence with

$$
\begin{align*}
& c_{0}=u_{o}=-L \\
& c_{i}=0 \quad \text { for } i \geq 1 \tag{57}
\end{align*}
$$

Thus, from (53), for the transformed sequence $\left\{(A u)_{n}\right\}$,

$$
\begin{align*}
\Delta_{p, p}(A u)_{N}= & c_{0} \Delta_{p, p}\left(\beta_{N, 0}\right)+c_{1} \Delta_{p, p}\left(\beta_{N, 1}\right) \\
& +\sum_{i=2}^{\infty} c_{i} \Delta_{p, p}\left(\beta_{N, i}\right)=-L^{2}<0, \tag{58}
\end{align*}
$$

which contradicts that $\left\{(A u)_{n}\right\}$ must be ( $\left.p, p\right)$-convex.
Next, suppose that the condition (ii) is not true. This case can be settled by a similar argument by considering the following sequence:

$$
\begin{equation*}
v=\left\{0,-L,-2 p L,-3 p^{2} L, \ldots\right\}, \tag{59}
\end{equation*}
$$

which implies that

$$
\begin{align*}
& c_{0}=0 \\
& c_{1}=-L  \tag{60}\\
& c_{i}=0 \quad \text { for } i \geq 2 .
\end{align*}
$$

Now, suppose that the condition (iii) is not true. Then there exists an integer $j \geq 2$ such that the $j$ th column-sequence of the matrix $\left[\beta_{n, k}\right.$ ] is not $(p, p)$-convex. That is, for some $N \geq 2$,

$$
\begin{equation*}
\Delta_{p, p}\left(\beta_{N, j}\right)=L<0 . \tag{61}
\end{equation*}
$$

Consider the ( $p, p$ )-convex sequence:

$$
\begin{align*}
x=\{ & \left\{0, \ldots, 0,1,2 p, 3 p^{2}, \ldots\right\} .  \tag{62}\\
& \underset{x_{0}}{\downarrow} \underset{x_{j-1} x_{j} x_{j+1}}{\downarrow} \underset{\sim}{\downarrow}
\end{align*}
$$

We see that, as in the proof of Theorem 2,

$$
\begin{equation*}
\Delta_{p, p}(A x)_{N}=L<0 \tag{63}
\end{equation*}
$$

which contradicts that $\{A x\}$ is a $(p, p)$-convex sequence.
We see that the result on the convexity of sequences given in [3, p. 331] is a particular case of Theorem 3 when $p=q=$ 1. Also, this theorem generalizes the necessary and sufficient conditions for a triangular matrix given in [9, p. 4].

## 4. Examples

We give below examples of $(p, q)$-convexity preserving matrices for each of the cases (a) through (h) given in (13) and (22).

Example for Case (a). Considering $0<p, q<1$, and $p \neq q$, we can assume, without loss of generality, that $p<q$. Let the matrix $A=\left[a_{n, k}\right]$ be defined by

$$
a_{n, k}= \begin{cases}p^{n}, & \text { if } k=0  \tag{64}\\ \frac{p^{n} q^{k}}{k}, & \text { if } k \geq 1\end{cases}
$$

Then, for each $n$,

$$
\begin{equation*}
\sum_{k=1}^{\infty} k a_{n, k}=\sum_{k=1}^{\infty} p^{n} q^{k}=p^{n}\left(\frac{q}{1-q}\right)<\infty . \tag{65}
\end{equation*}
$$

Thus, by (14), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 2 because, for $n \geq 2$, using (12),

$$
\begin{equation*}
\Delta_{p, q}\left(\beta_{n, i}\right)=\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-q^{j-i+1}}{p-q}\right) \Delta_{p, q}\left(a_{n, j}\right), \tag{66}
\end{equation*}
$$

in which

$$
\begin{align*}
& \Delta_{p, q}\left(a_{n, j}\right)=a_{n, j}-(p+q) a_{n-1, j}+p q a_{n-2, j} \\
& \quad= \begin{cases}p^{n}-(p+q) p^{n-1}+p q p^{n-2}, & \text { if } j=0, \\
\frac{q^{j}}{j}\left(p^{n}-(p+q) p^{n-1}+p q p^{n-2}\right), & \text { if } j \geq 1\end{cases} \tag{67}
\end{align*}
$$

$$
=0
$$

Therefore, the matrix $A$ preserves $(p, q)$-convexity of sequences.

Example for Case (b). Considering $0<p<1, q=1$, let the matrix $A=\left[a_{n, k}\right]$ be defined by

$$
\begin{equation*}
a_{n, k}=p^{k} \tag{68}
\end{equation*}
$$

Then, for each $n$,

$$
\begin{equation*}
\sum_{k=0}^{\infty} a_{n, k}=\sum_{k=0}^{\infty} p^{k}=\frac{1}{1-p}<\infty \tag{69}
\end{equation*}
$$

Thus, by (16), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 2 because, for $n \geq 2$, using (12),

$$
\begin{equation*}
\Delta_{p, 1}\left(\beta_{n, i}\right)=\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-1}{p-1}\right) \Delta_{p, 1}\left(a_{n, j}\right), \tag{70}
\end{equation*}
$$

in which

$$
\begin{align*}
\Delta_{p, 1}\left(a_{n, j}\right) & =a_{n, j}-(p+1) a_{n-1, j}+p a_{n-2, j}  \tag{71}\\
& =p^{j}-(p+1) p^{j}+p^{j+1}=0 .
\end{align*}
$$

Therefore, the matrix $A$ preserves $(p, 1)$-convexity of sequences.

Example for Case (c). Considering $p>1, q=1$, let matrix $A=\left[a_{n, k}\right]$ be defined by

$$
\begin{equation*}
a_{n, k}=\frac{1}{p^{2 k}} . \tag{72}
\end{equation*}
$$

Then, for each $n$,

$$
\begin{equation*}
\sum_{k=0}^{\infty} p^{k} a_{n, k}=\sum_{k=0}^{\infty} \frac{1}{p^{k}}=\frac{1}{1-1 / p}<\infty \tag{73}
\end{equation*}
$$

Thus, by (18), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 2 because, for $n \geq 2$, as in the previous example (b),

$$
\begin{align*}
\Delta_{p, 1}\left(a_{n, j}\right) & =a_{n, j}-(p+1) a_{n-1, j}+p a_{n-2, j} \\
& =\frac{1}{p^{2 j}}-(p+1) \frac{1}{p^{2 j}}+p \frac{1}{p^{2 j}}=0 . \tag{74}
\end{align*}
$$

Therefore, the matrix $A$ preserves $(p, 1)$-convexity of sequences.

Example for Case (d). Considering $p>1,0<q<1$, let matrix $A=\left[a_{n, k}\right]$ be defined by

$$
\begin{equation*}
a_{n, k}=p^{n-2 k} \tag{75}
\end{equation*}
$$

Then, for each $n$,

$$
\begin{equation*}
\sum_{k=0}^{\infty} p^{k} a_{n, k}=\sum_{k=0}^{\infty} p^{n-k}=\frac{p^{n+1}}{p-1}<\infty \tag{76}
\end{equation*}
$$

Thus, by (18), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 2 because, for $n \geq 2$, using (12),

$$
\begin{equation*}
\Delta_{p, q}\left(\beta_{n, i}\right)=\sum_{j=i}^{\infty}\left(\frac{p^{j-i+1}-q^{j-i+1}}{p-q}\right) \Delta_{p, q}\left(a_{n, j}\right) \tag{77}
\end{equation*}
$$

in which

$$
\begin{align*}
\Delta_{p, q}\left(a_{n, j}\right) & =a_{n, j}-(p+q) a_{n-1, j}+p q a_{n-2, j} \\
& =\frac{1}{p^{2 j}}\left(p^{n}-(p+q) p^{n-1}+p q p^{n-2}\right)=0 \tag{78}
\end{align*}
$$

Therefore, the matrix $A$ preserves $(p, q)$-convexity of sequences.

Example for Case (e). Considering $p, q>1$ and $p \neq q$, we can assume, without loss of generality, that $p>q$. Let the matrix $A=\left[a_{n, k}\right]$ be defined by

$$
\begin{equation*}
a_{n, k}=p^{n-2 k} q^{k} . \tag{79}
\end{equation*}
$$

Then, for each $n$,

$$
\begin{equation*}
\sum_{k=0}^{\infty} p^{k} a_{n, k}=p^{n} \sum_{k=0}^{\infty}\left(\frac{q}{p}\right)^{k}=\frac{p^{n+1}}{p-q}<\infty . \tag{80}
\end{equation*}
$$

Thus, by (18), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 2 because, for $n \geq 2$, as in the previous example (d),

$$
\begin{align*}
\Delta_{p, q}\left(a_{n, j}\right) & =a_{n, j}-(p+q) a_{n-1, j}+p q a_{n-2, j} \\
& =\frac{q^{j}}{p^{2 j}}\left(p^{n}-(p+q) p^{n-1}+p q p^{n-2}\right)=0 . \tag{81}
\end{align*}
$$

Therefore, the matrix $A$ preserves $(p, q)$-convexity of sequences.

Example for Case (f). Considering $0<p=q<1$, let the matrix $A=\left[a_{n, k}\right]$ be defined by

$$
a_{n, k}= \begin{cases}p^{n}, & \text { if } k=0  \tag{82}\\ \frac{p^{n+k}}{k}, & \text { if } k \geq 1\end{cases}
$$

Then, for each $n$,

$$
\begin{equation*}
\sum_{k=1}^{\infty} k a_{n, k}=\sum_{k=1}^{\infty} p^{n+k}=p^{n} \sum_{k=1}^{\infty} p^{k}=p^{n+1}\left(\frac{1}{1-p}\right)<\infty . \tag{83}
\end{equation*}
$$

Thus, by (23), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 3 because, for $n \geq 2$, using (12),

$$
\begin{equation*}
\Delta_{p, p}\left(\beta_{n, i}\right)=\sum_{j=i}^{\infty}(j-i+1) p^{j-i} \Delta_{p, p}\left(a_{n, j}\right) \tag{84}
\end{equation*}
$$

in which

$$
\begin{align*}
& \Delta_{p, p}\left(a_{n, j}\right)=a_{n, j}-2 p a_{n-1, j}+p^{2} a_{n-2, j} \\
& \quad=\left\{\begin{array}{ll}
p^{n}-2 p p^{n-1}+p^{2} p^{n-2}, & \text { if } j=0, \\
\frac{p^{j}}{j}\left(p^{n}-2 p p^{n-1}+p^{2} p^{n-2}\right), & \text { if } j \geq 1
\end{array}=0 .\right. \tag{85}
\end{align*}
$$

Therefore, the matrix $A$ preserves $(p, p)$-convexity of sequences.

Examples for Case (g). They can be found in [3], since $\Delta_{1,1}$ is the same as the second-order convexity $\Delta^{2}$.

Example for Case (h). Considering $p=q>1$, let the matrix $A=\left[a_{n, k}\right]$ be defined by

$$
a_{n, k}= \begin{cases}p^{n}(n+2), & \text { if } k=0  \tag{86}\\ \frac{p^{n-2 k}(n+2)}{k}, & \text { if } k \geq 1\end{cases}
$$

Therefore, for each $n$,

$$
\begin{align*}
\sum_{k=1}^{\infty} k p^{k} a_{n, k} & =\sum_{k=1}^{\infty} p^{n-k}(n+2)=p^{n}(n+2) \sum_{k=1}^{\infty}\left(\frac{1}{p}\right)^{k} \\
& =(n+2) \frac{p^{n}}{p-1}<\infty \tag{87}
\end{align*}
$$

Thus, by (23), $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2, \ldots$. The matrix $A$ satisfies the three conditions of Theorem 3 because, for $n \geq 2$, using (12),

$$
\begin{equation*}
\Delta_{p, p}\left(\beta_{n, i}\right)=\sum_{j=i}^{\infty}(j-i+1) p^{j-i} \Delta_{p, p}\left(a_{n, j}\right) \tag{88}
\end{equation*}
$$

in which

$$
\begin{align*}
& \Delta_{p, p}\left(a_{n, j}\right)=a_{n, j}-2 p a_{n-1, j}+p^{2} a_{n-2, j} \\
& = \begin{cases}p^{n}(n+2)-2 p^{n}(n+1)+p^{n} n & \text { if } j=0 \\
\frac{(n+2) p^{n-2 j}}{j}-2 \frac{(n+1) p^{n-2 j}}{j}+\frac{n p^{n-2 j}}{j}, & \text { if } j \geq 1\end{cases} \tag{89}
\end{align*}
$$

$$
=0 .
$$

Therefore, the matrix $A$ preserves the convexity of sequences.
We conclude this paper by giving an example of an infinite matrix which does not preserve ( $p, q$ )-convexity of sequences.

It is interesting to notice that the Borel matrix preserves the $(1,1)$-convexity of sequences $[3, p .336]$, but it does not preserve $(p, p)$-convexity when $p \neq 1$.

The Borel matrix $B=\left[b_{n, k}\right]$ is defined by

$$
\begin{equation*}
b_{n, k}=\frac{n^{k}}{e^{n} k!} \tag{90}
\end{equation*}
$$

Then, for each $n$,

$$
\begin{align*}
\sum_{k=1}^{\infty} k b_{n, k} & =\frac{n}{e^{n}} \sum_{k=1}^{\infty} \frac{n^{k-1}}{(k-1)!}=n<\infty  \tag{91}\\
\sum_{k=1}^{\infty} k p^{k} b_{n, k} & =\frac{(n p)}{e^{n}} \sum_{k=1}^{\infty} \frac{(n p)^{k-1}}{(k-1)!}=\frac{(n p)}{e^{n}} e^{n p}<\infty . \tag{92}
\end{align*}
$$

Thus, for each of the cases, $0<p<1$ and $p>1$, we see that (23) and (25) are satisfied and hence $\beta_{n, i}$ is well-defined for $n=0,1,2, \ldots$ and $i=0,1,2 \ldots$.

From (11),

$$
\begin{equation*}
\beta_{n, i}=\sum_{j=i}^{\infty}(j-i+1) p^{j-i} b_{n, j} \tag{93}
\end{equation*}
$$

Therefore,

$$
\begin{align*}
\beta_{n, 0} & =\sum_{j=0}^{\infty}(j+1) p^{j} \frac{n^{j}}{e^{n} j!} \\
& =\frac{1}{e^{n}}\left(\sum_{j=0}^{\infty} \frac{j(p n)^{j}}{j!}+\sum_{j=0}^{\infty} \frac{(p n)^{j}}{j!}\right)  \tag{94}\\
& =\frac{1}{e^{n}}\left(p n e^{p n}+e^{p n}\right)=e^{n(p-1)}(p n+1),
\end{align*}
$$

which implies that

$$
\begin{align*}
\Delta_{p, p} & \left(\beta_{n, 0}\right)=\beta_{n, 0}-2 p \beta_{n-1,0}+p^{2} \beta_{n-2,0} \\
= & e^{n(p-1)}(p n+1)-2 p e^{(n-1)(p-1)}(p(n-1)+1) \\
& \quad+p^{2} e^{(n-2)(p-1)}(p(n-2)+1)  \tag{95}\\
= & \frac{e^{n(p-1)}}{e^{2 p}}\left((p n+1)\left(e^{p}-p e\right)^{2}+2 p^{2} e\left(e^{p}-p e\right)\right) \\
> & 0
\end{align*}
$$

since $e^{p}-p e>0$ when $p \neq 1$. Thus, the condition (i) of Theorem 3 fails in the case of Borel matrix.

## Conflicts of Interest
