Abstract

We analyze the differences between the horizontal and the vertical component of the simple random walk on the 2-dimensional comb. In particular we evaluate by combinatorial methods the asymptotic behaviour of the expected value of the distance from the origin, the maximal deviation and the maximal span in n steps, proving that for all these quantities the order is $n^{1/4}$ for the horizontal projection and $n^{1/2}$ for the vertical one (the exact constants are determined). Then we rescale the two projections of the random walk dividing by $n^{1/4}$ and $n^{1/2}$ the horizontal and vertical ones, respectively. The limit process is obtained. With similar techniques the walk dimension is determined, showing that the Einstein relation between the fractal, spectral and walk dimensions does not hold on the comb

Key words: Random Walk, Maximal Excursion, Generating Function, Comb, Brownian Motion

Figure 1: The 2-dimensional comb.

1 Introduction and main results

The 2-dimensional comb \mathbf{C}_2 is maybe the simplest example of inhomogeneous graph. It is obtained from \mathbb{Z}^2 by removing all horizontal edges off the x -axis (see Figure 1). Many features of the simple random walk on this graph has been matter of former investigations. Local limit theorems were first obtained by Weiss and Havlin (19) and then extended to higher dimensions by Gerl (10) and Cassi and Regina (4). More recently, Krishnapur and Peres (14) have shown that on \mathbf{C}_2 two independent walkers meet only finitely many times almost surely. This result, together with the space-time asymptotic estimates obtained in (3) for the n -step transition probabilities, suggests that the walker spends most of the time on some tooth of the comb, that is moving along the vertical direction. Indeed in (3, Section 10), it has been remarked that, if k/n goes to zero with a certain speed, then $p^{(2n)}((2k, 0), (0, 0)) / p^{(2n)}((0, 2k), (0, 0)) \xrightarrow{n \rightarrow \infty} 0$.

Moreover the results in (3) imply that there are no sub-Gaussian estimate of the transition probabilities on \mathbf{C}_2 . Such estimates have been found on many graphs: by Jones (12) on the 2-dimensional Sierpiński graph, by Barlow and Bass (1) on the graphical Sierpiński carpet and on rather general graphs by Grigor'yan and Telcs ((11; 18)). These estimates involve three exponents which are usually associated to infinite graphs: the *spectral dimension* δ_s (which is by definition twice the exponent of n^{-1} in local limit theorems), the *fractal dimension* δ_f (which is the growth exponent) and the *walk dimension* δ_w (by definition the expected time until the first exit from the n -ball around the starting point is of order n^{δ_w}). These dimensions are in typical cases linked by the so-called *Einstein relation*: $\delta_s \delta_w = 2\delta_f$ (see Telcs (16; 17)). The first two dimensions are known for \mathbf{C}_2 : $\delta_s = 3/2$ and $\delta_f = 2$. In this paper we compute $\delta_w = 2$, thus showing that the relation does not hold for this graph.

In order to point out the different behaviour of the random walk along the two directions we analyze the asymptotic behaviour of the expected values of the horizontal and vertical distances reached by the walker in n steps. Different concepts of distance are considered: position after n steps, maximal deviation and maximal span (see Section 2 for the definitions).

Studying the projections of the random walk onto the two axes one observes that the vertical projection is the simple random walk on \mathbb{Z} with the addition of a loop at 0. It is known that

the expected values of the “distances” (i.e. position, maximal deviation and maximal span) in n steps for the simple random walk on \mathbb{Z} are of order $n^{1/2}$ (the estimates for the maximal deviation and maximal span were obtained by combinatorial methods by Panny and Prodinger in (15)). By comparison it is clear that the asymptotics coincide (to leading order) with the corresponding estimates for the vertical projection of the simple random walk on \mathbf{C}_2 . We sketch the ideas of the proof at the end of Section 2.

The behaviour of the horizontal projection of the random walk is less obvious: in Sections 3, 4 and 5 we prove that the expected values of the horizontal distance, of its maximal deviation and of its maximal span after n steps are all of order $n^{1/4}$ (the exact constants are determined in Theorem 3.1, Theorem 4.4 and Theorem 5.1 respectively).

The proofs are based on a Darboux type transfer theorem: we refer to (9, Corollary 2), but one may also refer to (2) and to the Hardy-Littlewood-Karamata theorem (see for instance (8)). This theorem (as far as we are concerned) claims that if

$$F(z) := \sum_{n=0}^{\infty} a_n z^n \stackrel{z \rightarrow 1^-}{\sim} \frac{C}{(1-z)^\alpha}, \quad \alpha \notin \{0, -1, -2, \dots\},$$

and $F(z)$ is analytic in some domain, with the exception of $z = 1$, then

$$a_n \stackrel{n \rightarrow \infty}{\sim} \frac{C}{\Gamma(\alpha)} n^{\alpha-1},$$

(by $a_n \sim b_n$ we mean that $a_n/b_n \xrightarrow{n \rightarrow \infty} 1$). Hence the aim of our computation is to determine an explicit expression of the generating functions of the sequences of expected values of the random variables we are interested in. This is done employing the combinatorial methods used by Panny and Prodinger in (15).

Since the notions of maximal deviation in n steps and of first exit time from a k -ball are closely related, we determine the walk dimension of \mathbf{C}_2 in Section 4. This is again done by comparison with the simple random walk on \mathbb{Z} .

In Section 6 we deal with the limit of the process obtained dividing by $n^{1/4}$ and by $n^{1/2}$ respectively the continuous time interpolation of the horizontal and vertical projections of the position after n steps. As one would expect the limit of the vertical component is the Brownian motion, while the limit of the horizontal component is less obvious (it is a Brownian motion indexed by the local time at 0 of the vertical component). This scaling limit is determined in Theorem 6.1.

Finally, Section 7 is devoted to a discussion of the results, remarks and open questions.

2 Preliminaries and vertical estimates

The simple random walk on a graph is a sequence of random variables $\{S_n\}_{n \geq 0}$, where S_n represents the position of the walker at time n , and if x and y are vertices which are neighbours then

$$p(x, y) := \mathbb{P}(S_{n+1} = y | S_n = x) = \frac{1}{\deg(x)},$$

where $\deg(x)$ is the number of neighbours of x , otherwise $p(x, y) = 0$. In particular on \mathbf{C}_2 the non-zero transition probabilities $p(x, y)$ are equal to $1/4$ if x is on the horizontal axis, and they are equal to $1/2$ otherwise.

Given $x, y \in \mathbf{C}_2$, let

$$p^{(n)}(x, y) := \mathbb{P}(S_n = y | S_0 = x), \quad n \geq 0,$$

be the n -step transition probability from x to y and $\mathbb{P}(S_0 = (0, 0)) = 1$. Recall that the generating function of a sequence $\{a_n\}_{n \geq 0}$ is the power series $\sum_{n \geq 0} a_n z^n$; by definition the Green function associated to the random walk on a graph X is the family of generating functions of the sequences $\{p^{(n)}(x, y)\}_{n \geq 0}$, $x, y \in X$, that is

$$G(x, y | z) = \sum_{n \geq 0} p^{(n)}(x, y) z^n.$$

The Green function, with $x = (0, 0)$, on \mathbf{C}_2 can be written explicitly as (see (3))

$$G((0, 0), (k, l) | z) = \begin{cases} \frac{1}{2} G(z) (F_1(z))^{|k|} (F_2(z))^{|l|}, & \text{if } l \neq 0, \\ G(z) (F_1(z))^{|k|}, & \text{if } l = 0, \end{cases}$$

where

$$\begin{aligned} G(z) &= \frac{\sqrt{2}}{\sqrt{1-z^2} + \sqrt{1-z^2}}; \\ F_1(z) &= \frac{1 + \sqrt{1-z^2} - \sqrt{2}\sqrt{1-z^2} + \sqrt{1-z^2}}{z}; \\ F_2(z) &= \frac{1 - \sqrt{1-z^2}}{z}. \end{aligned}$$

We refer to (21, Section 1.1) for more details on the random walks on graphs, transition probabilities and generating functions.

An interesting feature of a random walk is the distance reached in n steps. This distance may be defined as $\|S_n\|$, the distance at time n from the starting point, $\|\cdot\|$ denoting a suitable norm. On \mathbf{C}_2 the choice is between the usual distance on the graph $\|(x, y)\|_1 = |x| + |y|$ and $\|(x, y)\|_\infty = \max\{|x|, |y|\}$.

Other ‘‘distances’’ are the maximal deviation and the maximal span in n steps.

Definition 2.1. [a.]

1. The maximal deviation in n steps is defined as

$$D_n := \max\{\|S_i\| : 0 \leq i \leq n\}.$$

2. The maximal span in n steps is defined as

$$M_n := \max\{\|S_i - S_j\| : 0 \leq i, j \leq n\}.$$

When we need to stress the use of a particular norm $\|\cdot\|_+$, we use the notations $D_n(\|\cdot\|_+)$ and $M_n(\|\cdot\|_+)$. In order to deal with the two components of the walk, we write $S_n = (S_n^x, S_n^y)$ and denote by D_n^x and D_n^y the maximal deviations of the two processes $\{S_n^x\}_{n \geq 0}$ and $\{S_n^y\}_{n \geq 0}$ (defined on \mathbb{Z}) respectively. By M_n^x and M_n^y we denote the corresponding maximal deviations.

Figure 2: The vertical component of the simple random walk on \mathbf{C}_2 .

Moreover we denote by $|\cdot|$ the usual norm on \mathbb{Z} . It is worth noting that on \mathbb{Z} the maximal span may be equivalently defined as $\max\{S_i - S_j : 0 \leq i, j \leq n\}$.

Among the issues of this paper are the asymptotics of $\mathbb{E}(|S_n^*|)$, $\mathbb{E}(D_n^*)$ and $\mathbb{E}(M_n^*)$, where $*$ is either x or y .

Let us note that the asymptotics of the vertical component are already determined since they coincide (to leading order) with the corresponding estimates for the simple random walk on \mathbb{Z} . Indeed the vertical component of the simple random walk on \mathbf{C}_2 (represented in Figure 2) differs from the simple random walk on \mathbb{Z} only in the presence of the loop at 0. Hence we may associate to $\{S_n^y\}_{n \geq 0}$ two sequences of random variables: $\{Y_n'\}_{n \geq 0}$ and $\{L_n\}_{n \geq 0}$, such that $\{Y_n'\}_{n \geq 0}$ is a simple random walk on \mathbb{Z} , and L_n is the number of loops performed by $\{S_n^y\}_{n \geq 0}$ up to time n . Thus $S_n^y = Y_n' - E_n$, where the error term E_n is the (random) sum of L_n iid random variables Z_i with $\mathbb{P}(Z_i = \pm 1) = \frac{1}{2}$. One easily proves that E_n is negligible in all three estimates (for more details about Y_n' and L_n see Section 6).

For the simple random walk Y_n' on \mathbb{Z} , $\mathbb{E}[|Y_n'|] \sim \sqrt{2/\pi} n^{1/2}$ may be obtained from the generating function of the walk using the technique of Theorem 3.1, while the asymptotics of its maximal deviation, $\sqrt{\pi/2} n^{1/2}$, and of its maximal span, $\sqrt{8/\pi} n^{1/2}$, may be found in (15) (Theorem 2.14 and Theorem 3.4 respectively). Thus the following result is obvious.

Theorem 2.2. [a.]

1. $\mathbb{E}[|S_n^y|] \stackrel{n \rightarrow \infty}{\sim} \sqrt{\frac{2}{\pi}} n^{1/2};$
2. $\mathbb{E}[D_n^y] \stackrel{n \rightarrow \infty}{\sim} \sqrt{\frac{\pi}{2}} n^{1/2};$
3. $\mathbb{E}[M_n^y] \stackrel{n \rightarrow \infty}{\sim} \sqrt{\frac{8}{\pi}} n^{1/2}.$

3 Mean distance

The estimate of $\mathbb{E}[|S_n^x|]$ is quite easy and may be considered as a warm-up for the use of generating functions techniques.

Theorem 3.1.

$$\mathbb{E}[|S_n^x|] \stackrel{n \rightarrow \infty}{\sim} \frac{1}{2^{3/4} \Gamma(5/4)} n^{1/4}.$$

Proof. Since for $k \neq 0$,

$$\mathbb{P}(|S_n^x| = k) = 2 \sum_{l \in \mathbb{Z}} p^{(n)}((0, 0), (k, l)),$$

it is clear that (exchanging the order of summation)

$$\sum_{n=0}^{\infty} \mathbb{E}[|S_n^x|] z^n = 2 \sum_{k=1}^{\infty} k \sum_{l \in \mathbb{Z}} G((0,0), (k,l)|z).$$

By elementary computation one obtains

$$\begin{aligned} \sum_{n=0}^{\infty} \mathbb{E}[|S_n^x|] z^n &= G(z) \frac{F_1(z)}{(1-F_1(z))^2} \frac{1}{1-F_2(z)} \\ &\underset{z \rightarrow 1^-}{\sim} \frac{1}{2^{3/4}(1-z)^{5/4}}. \end{aligned}$$

Thus, applying (9, Corollary 2) we obtain the claim. □

The following Corollary is now trivial.

Corollary 3.2. *On \mathbf{C}_2 , $\mathbb{E}[||S_n||_1]$ and $\mathbb{E}[||S_n||_\infty]$ are both asymptotic, as n goes to infinity, to $\sqrt{\frac{2}{\pi}} n^{1/2}$.*

4 Mean maximal deviation and walk dimension

4.1 Maximal horizontal deviation

In order to compute the generating function of $\{\mathbb{E}[D_n^x]\}_{n \geq 0}$, we first need an expression for another generating function.

Lemma 4.1. *Let $h \in \mathbb{N}$, $l \in \{0, \dots, h\}$. The generating function of the sequence $\{\mathbb{P}(D_n^x \leq h, S_n^x = l)\}_{n \geq 0}$ is*

$$\psi_{h,l} \left(\frac{1 - \sqrt{1 - z^2}}{2z} \right) \cdot \frac{2(1 - \sqrt{1 - z^2})}{z(\sqrt{1 - z^2} - 1 + z)},$$

where $\psi_{h,l}(z)$ is the generating function of the number of paths on \mathbb{Z} of length n , from 0 to l with maximal deviation less or equal to h .

Proof. Note that the paths we are interested in have no bound on the vertical excursions. Thus we may decompose the walk into its horizontal and vertical components, and consider each horizontal step as a vertical excursion (whose length might be zero) coming back to the origin plus a step along the horizontal direction.

Keeping this decomposition in mind, it is clear that the generating function of the sequence $\{\mathbb{P}(D_n^x \leq h, S_n = (l, 0))\}_{n \geq 0}$ is

$$\psi_{h,l} \left(\frac{z \tilde{G}(0,0|z)}{4} \right),$$

where $\tilde{G}(0, j|z)$ is the generating function of the probabilities of the n -step excursions along one single tooth of the comb (that is paths in Figure 2 which do not use the loop at zero), from $(x, 0)$ to (x, j) .

Moreover we must admit a final excursion from $(l, 0)$ to (l, j) for some $j \in \mathbb{Z}$, that is we must multiply by

$$E(z) := \tilde{G}(0, 0|z) + 2 \sum_{j=1}^{\infty} \tilde{G}(0, j|z),$$

and the generating function of $\{\mathbb{P}(D_n^x \leq h, S_n^x = l)\}_{n \geq 0}$ is

$$\psi_{h,l} \left(\frac{z \tilde{G}(0, 0|z)}{4} \right) \cdot E(z).$$

Using (21, Lemma 1.13) and reversibility (see (21, Section 1.2.A)), it is not difficult to compute

$$\begin{aligned} \tilde{G}(0, 0|z) &= \frac{2(1 - \sqrt{1 - z^2})}{z^2}, \\ \tilde{G}(0, j|z) &= \frac{1}{2} \tilde{G}(0, 0|z) \left(\frac{1 - \sqrt{1 - z^2}}{z} \right)^j, \quad j \neq 0. \end{aligned}$$

The claim is obtained noting that

$$\begin{aligned} \frac{z \tilde{G}(0, 0|z)}{4} &= \frac{1 - \sqrt{1 - z^2}}{2z}, \\ E(z) &= \frac{2(1 - \sqrt{1 - z^2})}{z(\sqrt{1 - z^2} - 1 + z)}. \end{aligned}$$

□

Proposition 4.2.

$$\sum_{n=0}^{\infty} \mathbb{E}[D_n^x] z^n = 2 \frac{1 + 6v^2 + v^4}{(1 - v)^4} \sum_{h \geq 1} \frac{v^h}{1 + v^{2h}},$$

where v is such that

$$\frac{v}{1 + v^2} = \frac{1 - \sqrt{1 - z^2}}{2z}. \tag{1}$$

Proof. Let $\psi_{h,l}(z)$ be as in Lemma 4.1, and put $\psi_h(z) = \sum_{|l| \leq h} \psi_{h,l}(z)$. Then the generating function of $\{\mathbb{P}(D_n^x \leq h)\}_{n \geq 0}$ is

$$H_h(z) := \psi_h \left(\frac{1 - \sqrt{1 - z^2}}{2z} \right) \cdot \frac{2(1 - \sqrt{1 - z^2})}{z(\sqrt{1 - z^2} - 1 + z)}.$$

Thus we may write the generating function of $\mathbb{E}[D_n^x]$ as

$$\sum_{n=0}^{\infty} \left(\sum_{h=0}^{\infty} \mathbb{P}(D_n^x > h) \right) z^n = \sum_{h=0}^{\infty} \left(\frac{1}{1 - z} - H_h(z) \right). \tag{2}$$

An explicit expression for ψ_h has been determined by Panny and Prodinger in (15, Theorem 2.2):

$$\psi_h(w) = \frac{(1+v^2)(1-v^{h+1})^2}{(1-v)^2(1+v^{2h+2})},$$

where $w = v/(1+v^2)$. By the definition of $H_h(z)$ it is clear that the relation between z and v is set by equation (1). Then it is just a matter of computation to obtain

$$H_h(z) = \frac{(1+6v^2+v^4)(1-v^{h+1})^2}{(1-v)^4(1+v^{2(h+1)})},$$

$$\frac{1}{1-z} = \frac{1+6v^2+v^4}{(1-v)^4},$$

whence, substituting in (2), the claim. □

Lemma 4.3.

$$\sum_{h \geq 1} \frac{v^h}{1+v^{2h}} \underset{v \rightarrow 1^-}{\sim} \frac{\pi}{4(1-v)}.$$

Proof. The proof is quite standard, we report it here for completeness. Put $v = e^{-t}$, $g(w) = e^{-w}/(1+e^{-2w})$ and consider

$$f(t) := \sum_{h \geq 1} \frac{e^{-ht}}{1+e^{-2ht}} = \sum_{h \geq 1} g(ht).$$

The Mellin transform of f is:

$$f^*(s) = \int_0^\infty \sum_{h \geq 1} g(ht) t^{s-1} dt$$

$$= \zeta(s) \int_0^\infty \sum_{\lambda \geq 0} (-1)^\lambda e^{-(2\lambda+1)w} w^{s-1} dw,$$

where $\zeta(s) = \sum_{h \geq 1} h^{-s}$ is the Riemann zeta function. The knowledge of the behaviour of $f^*(s)$ in a neighbourhood of 1, will give us the behaviour of $f(t)$ in a neighbourhood of 0. Substitute $y = (2\lambda+1)w$ to obtain

$$f^*(s) = \zeta(s) \kappa(s) \Gamma(s),$$

where $\kappa(s) = \sum_{\lambda \geq 0} \frac{(-1)^\lambda}{(1+2\lambda)^s}$, and $\Gamma(s) = \int_0^\infty e^{-y} y^{s-1} dy$ is the gamma function. Since as $s \rightarrow 1^+$

$$\zeta(s) = \frac{1}{s-1} + O(1),$$

$$\Gamma(s) = 1 + O(s-1),$$

we are left with the computation of the asymptotic behaviour of $\kappa(s)$. We may write

$$\kappa(s) = \frac{1}{4^s} (\zeta(s, 1/4) - \zeta(s, 3/4)),$$

where $\zeta(s, a) = \sum_{h \geq 0} (a+h)^{-s}$ is the Hurwitz zeta function. Thus using the expansion of $\zeta(s, a)$ for s close to 1 (see (20, Formula 13.21)) we obtain

$$\kappa(s) = \frac{\pi}{4} + O(s-1).$$

Hence we get

$$f^*(s) \stackrel{s \rightarrow 1^+}{\sim} \frac{\pi}{4(s-1)}.$$

Applying (6, Theorem 1, p.115),

$$f(t) \stackrel{t \rightarrow 0^+}{\sim} \frac{\pi}{4t},$$

which, substituting $t = -\log(1 - (1-v))$, gives the claim. \square

Theorem 4.4.

$$\mathbb{E}[D_n^x] \stackrel{n \rightarrow \infty}{\sim} \frac{2^{-7/4}\pi}{\Gamma(5/4)} n^{1/4}.$$

Proof. By Proposition 4.2 and Lemma 4.3, it is clear that

$$\sum_{n \geq 0} \mathbb{E}[D_n^x] z^n \stackrel{v \rightarrow 1^-}{\sim} \frac{4\pi}{(1-v)^5}. \quad (3)$$

Choosing the solution v of equation (1) which is smaller than 1 when z is smaller than 1, and substituting it in (3) we obtain

$$\sum_{n=0}^{\infty} \mathbb{E}[D_n^x] z^n \stackrel{z \rightarrow 1^-}{\sim} \frac{2^{-7/4}\pi}{(1-z)^{5/4}},$$

and (by (9, Corollary 2)) the claim. \square

Recalling Theorem 2.2, and the inequalities

$$D_n^y \leq \max_{0 \leq i \leq n} \|S_i\|_{\infty} \leq \max_{0 \leq i \leq n} \|S_i\|_1 \leq D_n^x + D_n^y.$$

the following corollary is obvious.

Corollary 4.5. *On \mathbf{C}_2 , both $\mathbb{E}[D_n(\|\cdot\|_1)]$ and $\mathbb{E}[D_n(\|\cdot\|_{\infty})]$, as n goes to infinity, are asymptotic to $\sqrt{\pi/2} n^{1/2}$.*

4.2 Walk dimension

The maximal deviation of a random walk is linked to the first exit time from a ball of radius k . Indeed if we put $T_k = \min\{i : S_i \notin B_k\}$, where B_k is the ball of radius k centered in $(0, 0)$, then

$$(D_n \leq k) = (T_k > n).$$

Clearly the radius of the ball and D_n must be computed with respect to the same norm on the graph. Usually one chooses the $\|\cdot\|_1$ norm (we write T_n^{∞} if $\|\cdot\|_{\infty}$ is considered). Indeed

this choice will not affect the definition of the walk dimension, which, as we recalled in the introduction, is defined for a graph G as $\delta_w(G) = \alpha$ if $\mathbb{E}[T_n]$ is of order n^α (and T_n is computed with respect to the simple random walk on G).

By the results obtained so far it is clear that on \mathbf{C}_2 , $\mathbb{E}[T_n]$ is of order n^2 , since $\delta_w(\mathbb{Z}) = 2$. It is perhaps less obvious that the exact asymptotics are n^2 and that this also holds when dealing with $\mathbb{E}[T_n^\infty]$.

The first asymptotics are obtained by comparison with the simple random walk on \mathbb{Z} : we sketch here the derivation of the asymptotics of $\mathbb{E}[T_n(\mathbb{Z})]$ via generating functions techniques. The behaviour of the latter sequence is well known, nevertheless we briefly report here a proof in order to give a hint as to how to prove $\mathbb{E}[T_n^\infty] \sim n^2$.

Proposition 4.6. $\mathbb{E}[T_n] \overset{n \rightarrow \infty}{\sim} n^2$ and $\mathbb{E}[T_n^\infty] \overset{n \rightarrow \infty}{\sim} n^2$.

Proof. We write

$$\mathbb{E}[T_n] = \sum_{k \geq 0} \mathbb{P}(T_n > k),$$

that is, $\mathbb{E}[T_n] = \Theta_n(1)$, where $\Theta_n(z)$ is the generating function of the sequence $\{\mathbb{P}(T_n > k)\}_{k \geq 0} = \{\mathbb{P}(\max_{0 \leq i \leq k} \|S_i\|_1 \leq n)\}_{k \geq 0}$. We claim that $\mathbb{P}(\max_{0 \leq i \leq k} \|S_i\|_1 \leq n) = \mathbb{P}(\max_{0 \leq i \leq k} \|\tilde{S}_i\| \leq n)$ where $\{\tilde{S}_i\}_{i \geq 0}$ is a suitable representation of the simple random walk on \mathbb{Z} . Indeed it suffices to consider the map that associates to each trajectory on \mathbf{C}_2 a trajectory on \mathbb{Z} which jumps from j to $j + 1$ whenever on \mathbf{C}_2 one of the two components increases and jumps from j to $j - 1$ otherwise (i.e. when one of the components decreases).

The generating function of the number of paths on \mathbb{Z} of length k , with maximal deviation smaller or equal to n is $\Psi_n(z) = \frac{(1+v^2)(1-v^{n+1})^2}{(1-v)^2(1+v^{2n+2})}$ with the substitution $z = v/(1+v^2)$, which was obtained in Theorem 2.2 of (15). Thus

$$\Theta_n(z) = \frac{(1+v^2)(1+v+\dots+v^n)^2}{(1+v^{2n+2})} \tag{4}$$

with the substitution $z = 2v/(1+v^2)$. For $z = v = 1$ we get $\Theta_n(1) = (n+1)^2$.

The same methods used for $\mathbb{E}[T_n]$ apply to the evaluation of $\mathbb{E}[T_n^\infty]$ (one only has to carefully decompose the walk much in the spirit of what was done in Lemma 4.1). The proof of this last estimate is omitted. \square

Corollary 4.7. *The walk dimension of \mathbf{C}_2 is equal to 2.*

5 Mean maximal span

Theorem 5.1. $\mathbb{E}[M_n^x] \overset{n \rightarrow \infty}{\sim} \frac{2^{1/4}}{\Gamma(5/4)} n^{1/4}$.

Proof. Let $m_n^x = \max\{S_i^x : 0 \leq i \leq n\}$. Then it is clear that $\mathbb{E}[M_n^x] = 2\mathbb{E}[m_n^x]$. Our first aim is to compute the generating function of $\{\mathbb{P}(m_n^x \leq h)\}_{n \geq 0}$, which we denote by $\tilde{\Psi}_h(z)$. Then

$$\tilde{\Psi}_h(z) = \lim_{k \rightarrow \infty} \sum_{l=-k}^h \tilde{\Psi}_{h,k;l}(z) \cdot E(z),$$

where $\tilde{\Psi}_{h,k;l}(z)$ is the generating function of the probabilities of the n -step paths such that $-k \leq S_i^x \leq h$ for $0 \leq i \leq n$, $S_n = (l, 0)$ and $S_{n-1}^x \neq l$, while $E(z)$ was defined and computed in Lemma 4.1. Let us note that $\tilde{\Psi}_{h,k;l}(z) = \Psi_{h,k;l}(z\tilde{G}(0, 0|z)/4)$, where $\Psi_{h,k;l}(z)$ is the generating function of the number of the n -step paths on \mathbb{Z} which stay in the interval between $-k$ and h , and end at l . The functions $\Psi_{h,k;l}(w)$ are determined by the linear system used in (15, Theorem 4.1) to determine $\Psi_{h,k;0}(w)$. Thus

$$\Psi_{h,k;l}(w) = \frac{w^l a_{h-l-1}(w) a_{k-1}(w)}{a_{h+k}(w)}, \text{ if } l \geq 0,$$

$$\Psi_{h,k;l}(w) = \frac{w^{-l} a_{h-1}(w) a_{k+l-1}(w)}{a_{h+k}(w)}, \text{ if } l \leq -1.$$

Then we put $w = z\tilde{G}(0, 0|z)/4 = v/(1 + v^2)$ and we obtain that (compare with the proof of Proposition 4.2)

$$\lim_{k \rightarrow \infty} \sum_{l=-k}^h \tilde{\Psi}_{h,k;l}(z) = \frac{(1 + v^2)(1 - v^{h+1})}{(1 - v)^2},$$

$$E(z) = \frac{1 + 6v^2 + v^4}{(1 + v^2)(1 - v)^2}.$$

Then

$$\tilde{\Psi}_h(z) = \frac{(1 + 6v^2 + v^4)(1 - v^{h+1})}{(1 - v)^4},$$

$$\sum_{n=0}^{\infty} \mathbb{E}[m_n^x] z^n = \frac{1 + 6v^2 + v^4}{(1 - v)^4} \sum_{h \geq 0} v^{h+1} z \stackrel{z \rightarrow 1^-}{\sim} \frac{1}{2^{3/4}(1 - z)^{5/4}},$$

whence $\mathbb{E}[m_n^x] \stackrel{n \rightarrow \infty}{\sim} 2^{-3/4} n^{1/4} / \Gamma(5/4)$ and we are done. \square

Corollary 5.2. *On \mathbf{C}_2 , both $\mathbb{E}[M_n(\|\cdot\|_1)]$ and $\mathbb{E}[M_n(\|\cdot\|_\infty)]$, as n goes to infinity, are asymptotic to $\sqrt{8/\pi} n^{1/2}$.*

6 Scaling limits

In the preceding sections we have seen that the expected values of the distances (with various meanings of this word) reached in n steps are of order $n^{1/4}$ for the horizontal direction and of order $n^{1/2}$ for the vertical direction. These results lead us to a natural question: what is the asymptotic behaviour of the process where the horizontal component of the position after n steps is divided by $n^{1/4}$ and the vertical component is divided by $n^{1/2}$? Of course we have to make this question more precise.

In order to study the scaling of the process we choose a suitable realization for the sequence $\{S_n\}_{n \geq 0}$: let $X = \{X_n\}_{n \geq 0}$ be a sequence of random variables representing a simple random walk on \mathbb{Z} , and $Y = \{Y_n\}_{n \geq 0}$ be a sequence representing the random walk on \mathbb{Z} moving according

to Figure 2. Choose X and Y to be independent and let $X_0 = Y_0 \equiv 0$ almost surely. Moreover, let L_k be the number of loops performed by Y up to time k , that is

$$L_k = \sum_{i=0}^{k-1} \mathbb{1}_{Y_i=0, Y_{i+1} \neq 0}.$$

Clearly, $S_n = (X_{L_n}, Y_n)$ is a realization of the position of the simple random walker on \mathbf{C}_2 at time n . We are now able to define, by linear interpolation of the three discrete time processes X, Y and L , a continuous time process $(X_{L_{nt}}, Y_{nt})$.

Theorem 6.1.

$$\left(\frac{X_{L_{nt}}}{\sqrt{n}}, \frac{Y_{nt}}{\sqrt{n}} \right)_{t \geq 0} \xrightarrow{\text{Law}} \left(W_{L_t^0(B)}, B_t \right)_{t \geq 0}, \quad (5)$$

where W and B are two independent Brownian motions and $L_t^0(B)$ is the local time at 0 of B .

The theorem will be a consequence of Proposition 6.4 and Proposition 6.5. We introduce the following notion of convergence of stochastic processes (see Definition 2.2 of (5)).

Definition 6.2. A sequence of \mathbb{R}^k -valued stochastic processes $(Z_t^n; t \geq 0)_{n \geq 0}$ converges to a process $(Z_t; t \geq 0)$ in probability uniformly on compact intervals if for all $t \geq 0$, as $n \rightarrow \infty$

$$\sup_{s \leq t} \|Z_s^n - Z_s\| \xrightarrow{\mathbb{P}} 0,$$

where $\|\cdot\|$ is a norm on \mathbb{R}^k (for instance $\|\cdot\|_1$). We will briefly write

$$(Z_t^n; t \geq 0) \xrightarrow{U.P.} (Z_t; t \geq 0).$$

Since U.P. convergence of a vector is equivalent to U.P. convergence of its components and implies convergence in distribution, in order to prove Theorem 6.1 it will suffice to prove that each component in (5) U.P. converges to the corresponding limit.

The main idea is that Y and L are not much different from, respectively, a simple random walk Y' on \mathbb{Z} and the process L' which counts the visits of Y' to 0. There is a natural correspondence between Y and Y' , so let us define Y' and some other auxiliary variables which will be needed in the sequel. Given Y , let l and N be the processes which respectively count its returns to 0 (not including the loops and counting time 0 as the first “return”) and the time spent not looping at 0. Namely, let $l_0 = 1$, and $l_k = 1 + \sum_{i=0}^{k-1} \mathbb{1}_{Y_{i+1} \neq 0, Y_i = 0}$ and $N_k = \sum_{i=0}^{k-1} \mathbb{1}_{Y_i \neq Y_{i+1}}$ for $k \geq 1$. Clearly $N_k = k - L_k$. Moreover, note that for $k \geq 1$,

$$\sum_{i=0}^{l_k-1} \tau_i \leq L_k \leq \sum_{i=0}^{l_k} \tau_i, \quad (6)$$

where $\tau = \{\tau_i\}_{i \geq 0}$ is a suitable sequence of iid random variables with geometric distribution of parameter $1/2$. Now define a simple random walk Y' on \mathbb{Z} by $Y_n = Y'_{N_n}$. Then $L'_k = \sum_{i=0}^k \mathbb{1}_{Y'_i=0}$ (L' counts the visits at 0 or, equivalently, the returns to 0). We note that $l_n = L'_{N_n}$ and $0 \leq l_n \leq L'_n$. We first prove a property of L .

Lemma 6.3.

$$\frac{L_n}{\sqrt{n}} \xrightarrow{\text{Law}} |\mathcal{N}(0, 1)|.$$

Proof. The main ideas of the proof are the facts that $L'_n/\sqrt{n} \rightarrow |\mathcal{N}(0, 1)|$ and that N_n is not much different from n . Indeed one can easily prove the first fact (for the distribution of $(L'_{2n} - 1)$ see (7, Chapter III, Exercise 10)). By (6), the claim is a consequence of

$$\frac{\sum_{i=0}^{l_n} \tau_i}{\sqrt{n}} \xrightarrow{\text{Law}} |\mathcal{N}(0, 1)|. \quad (7)$$

By the strong law of large numbers and Slutsky's theorem,

$$\frac{\sum_{i=0}^{L'_n} \tau_i}{\sqrt{n}} = \frac{\sum_{i=0}^{L'_n} \tau_i}{L'_n} \cdot \frac{L'_n}{\sqrt{n}} \xrightarrow{\text{Law}} |\mathcal{N}(0, 1)|.$$

Then (7) will follow once we show that $\sum_{i=0}^{l_n} \tau_i / \sum_{i=0}^{L'_n} \tau_i \xrightarrow{\mathbb{P}} 1$. Indeed note that

$$L'_n = L'_{N_n} + R'_n = l_n + R'_n, \quad (8)$$

where R'_n is the number of visits to 0 of Y' between time N_n and time n . Let T_n be the time Y' first visits 0 after time N_n , and for any $j \geq 0$ let L'_j be the number of visits to 0 before time j of the random walk $Y''_m := Y'_{m+T_n}$. Clearly L'_j is independent of $\{Y'_k\}_{k=0}^{N_n}$ and has the same distribution of L'_j . Then

$$\frac{\sum_{i=0}^{l_n} \tau_i}{\sum_{i=0}^{L'_n} \tau_i} = 1 - \frac{\sum_{i=l_n+1}^{L'_n} \tau_i}{\sum_{i=0}^{L'_n} \tau_i} = 1 - \frac{\sum_{i=1}^{R'_n} \tilde{\tau}_i}{\sum_{i=0}^{L'_n} \tau_i},$$

where $\tilde{\tau}_i = \tau_{i+l_n}$ and $\sum_{i=1}^{R'_n} \tilde{\tau}_i$ is equal to zero if $L'_n = l_n$. We are left with the proof that $\sum_{i=1}^{R'_n} \tilde{\tau}_i / \sum_{i=0}^{L'_n} \tau_i \xrightarrow{\mathbb{P}} 0$. Since $0 \leq R'_n \leq L''_{n-N_n}$, it suffices to prove that $\sum_{i=1}^{L''_{n-N_n}} \tilde{\tau}_i / \sum_{i=0}^{L'_n} \tau_i \xrightarrow{\mathbb{P}} 0$. Fix $\varepsilon > 0$: since $\sum_{i=0}^{L'_n} \tau_i \geq n - N_n$ we have that

$$\begin{aligned} \mathbb{P} \left(\frac{\sum_{i=1}^{L''_{n-N_n}} \tilde{\tau}_i}{\sum_{i=0}^{L'_n} \tau_i} > \varepsilon \right) &\leq \sum_{k=1}^n \mathbb{P} \left(\frac{\sum_{i=1}^{L''_{n-N_n}} \tilde{\tau}_i}{n - N_n} > \varepsilon, n - N_n = k \right) \\ &= \sum_{k=1}^n \mathbb{P} \left(\frac{\sum_{i=1}^{L''_k} \tilde{\tau}_i}{k} > \varepsilon \right) \mathbb{P}(n - N_n = k). \end{aligned}$$

Now fix $\delta > 0$ and choose $M = M(\delta)$ such that $\mathbb{P}(\sum_{i=1}^{L''_k} \tilde{\tau}_i/k > \varepsilon) < \delta$ for all $k \geq M$ (this is possible by the law of large numbers using the facts that L'' and $\tilde{\tau}$ are independent and $L''_k/k \xrightarrow{\mathbb{P}} 0$). Then

$$\sum_{k=1}^n \mathbb{P} \left(\frac{\sum_{i=1}^{L''_k} \tilde{\tau}_i}{k} > \varepsilon \right) \mathbb{P}(n - N_n = k) \leq \mathbb{P}(n - N_n < M) + \delta.$$

Since $n - N_n \xrightarrow{\mathbb{P}} \infty$ we are done. □

Proposition 6.4.

$$\left(\frac{1}{\sqrt{n}} Y_{nt}, \frac{1}{\sqrt{n}} L_{nt} \right)_{t \geq 0} \xrightarrow{U.P.} (B_t, L_t^0(B))_{t \geq 0}.$$

Proof. Consider the processes Y' and L' defined before Lemma 6.3 and by interpolation define the sequence of two-dimensional continuous time processes $\left(\left(\frac{1}{\sqrt{n}} Y'_{nt}, \frac{1}{\sqrt{n}} L'_{nt} \right); t \geq 0 \right)_{n \geq 0}$. Then by Theorem 3.1 of (5) we have that

$$\left(\frac{1}{\sqrt{n}} Y'_{nt}, \frac{1}{\sqrt{n}} L'_{nt} \right)_{t \geq 0} \xrightarrow{U.P.} (B_t, L_t^0(B))_{t \geq 0}.$$

To prove our statement, it suffices to show that these two properties hold:

$$(A) : \left(\frac{1}{\sqrt{n}} (Y_{[nt]} - Y'_{[nt]}) \right)_{t \geq 0} \xrightarrow{U.P.} 0$$

$$(B) : \left(\frac{1}{\sqrt{n}} (L_{[nt]} - L'_{[nt]}) \right)_{t \geq 0} \xrightarrow{U.P.} 0.$$

Note that Y' is the sum of iid increments ξ_i such that $\mathbb{P}(\xi_i = \pm 1) = 1/2$, hence

$$\begin{aligned} Y_{[nt]} &= Y'_{[nt] - L_{[nt]}} = \sum_{i=1}^{[nt] - L_{[nt]}} \xi_i \\ &= \sum_{i=1}^{[nt]} \xi_i - \sum_{i=[nt] - L_{[nt]} + 1}^{[nt]} \xi_i = Y'_{[nt]} - \sum_{i=1}^{L_{[nt]}} \tilde{\xi}_i, \end{aligned}$$

where $\tilde{\xi}_i = \xi_{[nt] - L_{[nt]} + i}$ (and $\sum_{i=1}^{L_{[nt]}} \tilde{\xi}_i = 0$ if $L_{[nt]} = 0$). Thus $Y_{[nt]} - Y'_{[nt]} = \sum_{i=1}^{L_{[nt]}} \tilde{\xi}_i$. Then (A) follows from

$$\sup_{s \leq t} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^{L_{[ns]}} \tilde{\xi}_i \right| \xrightarrow{\mathbb{P}} 0. \quad (9)$$

Indeed

$$\sup_{s \leq t} \left| \sum_{i=1}^{L_{[ns]}} \tilde{\xi}_i \right| \leq \max_{k \leq L_{[nt]}} \left| \sum_{i=1}^k \tilde{\xi}_i \right|,$$

and if we denote by $M_n = \max_{k \leq n} \sum_{i=1}^k \tilde{\xi}_i$ and by $m_n = \min_{k \leq n} \sum_{i=1}^k \tilde{\xi}_i$, clearly M_n and $-m_n$ are identically distributed, and $\max_{k \leq L_{[nt]}} \left| \sum_{i=1}^k \tilde{\xi}_i \right| = \max \left\{ M_{L_{[nt]}}, -m_{L_{[nt]}} \right\}$. Hence to prove (9) it suffices to show that

$$\frac{1}{\sqrt{n}} M_{L_{[nt]}} \xrightarrow{\mathbb{P}} 0.$$

The distribution of M_n is well known (see (7, Chapter III.7)), and it is easy to show that $M_n/\sqrt{n} \xrightarrow{Law} |\mathcal{N}(0, 1)|$. Noting that $L_{\lfloor nt \rfloor}$ is independent of M_k , we have that

$$\begin{aligned} \mathbb{P}(M_{L_{\lfloor nt \rfloor}} > \varepsilon\sqrt{n}) &= \sum_{k=0}^{\lfloor nt \rfloor} \mathbb{P}(M_k > \varepsilon\sqrt{n})\mathbb{P}(L_{\lfloor nt \rfloor} = k) \\ &\leq \sum_{\varepsilon\sqrt{n} < k \leq \alpha\sqrt{\lfloor nt \rfloor}} \mathbb{P}(M_k > \varepsilon\sqrt{n})\mathbb{P}(L_{\lfloor nt \rfloor} = k) + \sum_{k > \alpha\sqrt{\lfloor nt \rfloor}} \mathbb{P}(L_{\lfloor nt \rfloor} = k) \\ &\leq \mathbb{P}(M_{\lfloor \alpha\sqrt{\lfloor nt \rfloor} \rfloor} > \varepsilon\sqrt{n}) + \mathbb{P}(L_{\lfloor nt \rfloor} > \alpha\sqrt{\lfloor nt \rfloor}). \end{aligned}$$

By Lemma 6.3, for any positive ε' and t there exist α and n' such that $\mathbb{P}(L_{\lfloor nt \rfloor} > \alpha\sqrt{\lfloor nt \rfloor}) < \varepsilon'$ for all $n \geq n'$. On the other hand for any given ε, α

$$\mathbb{P}\left(\frac{M_{\lfloor \alpha\sqrt{\lfloor nt \rfloor} \rfloor}}{\sqrt{\alpha}\sqrt[4]{\lfloor nt \rfloor}} > \frac{\varepsilon\sqrt[4]{n}}{\sqrt{\alpha}\sqrt[4]{t}}\right) \xrightarrow{n \rightarrow \infty} 0,$$

whence (A) is proven.

Now, let us address to (B). We first note that we may consider a mapping between the number of steps taken by Y' and the ones taken by Y . Indeed when Y' has taken $\lfloor nt \rfloor$ steps, then Y has taken $\lfloor nt \rfloor + \sum_{i \leq L'_{\lfloor nt \rfloor}} \tau_i$ steps (that is, if $Y'_{\lfloor nt \rfloor} = 0$ we decide to count for Y all the loops it performs after this last return to 0). Let us write

$$\begin{aligned} \frac{1}{\sqrt{n}} \left(L'_{\lfloor nt \rfloor} - L_{\lfloor nt \rfloor} \right) &= \frac{1}{\sqrt{n}} \left(L'_{\lfloor nt \rfloor} - L_{\lfloor nt \rfloor + \sum_{i \leq L'_{\lfloor nt \rfloor}} \tau_i} \right) + \\ &\quad \frac{1}{\sqrt{n}} \left(L_{\lfloor nt \rfloor + \sum_{i \leq L'_{\lfloor nt \rfloor}} \tau_i} - L_{\lfloor nt \rfloor} \right) =: I + II. \end{aligned} \quad (10)$$

We prove that $I \xrightarrow{U.P.} 0$. Indeed $L_{\lfloor nt \rfloor + \sum_{i \leq L'_{\lfloor nt \rfloor}} \tau_i} = \sum_{i \leq L'_{\lfloor nt \rfloor}} \tau_i$, thus

$$\sup_{s \leq t} \left| L'_{\lfloor ns \rfloor} - \sum_{i \leq L'_{\lfloor ns \rfloor}} \tau_i \right| = \sup_{s \leq t} \left| \sum_{i \leq L'_{\lfloor ns \rfloor}} (1 - \tau_i) \right| \leq \max_{k \leq L'_{\lfloor nt \rfloor}} \left| \sum_{i \leq k} (1 - \tau_i) \right|.$$

Now choose $\delta > 0$. By independence of L' and τ we have that the probability that $\max_{k \leq L'_{\lfloor nt \rfloor}} \left| \sum_{i \leq k} (1 - \tau_i) \right|$ is larger than $\varepsilon\sqrt{n}$ is bounded by

$$\mathbb{P}\left(L'_{\lfloor nt \rfloor} > \alpha\sqrt{\lfloor nt \rfloor}\right) + \sum_{j \leq \alpha\sqrt{\lfloor nt \rfloor}} \mathbb{P}\left(\max_{k \leq j} \left| \sum_{i \leq k} (1 - \tau_i) \right| > \varepsilon\sqrt{n}\right) \mathbb{P}\left(L'_{\lfloor nt \rfloor} = j\right).$$

The first term is smaller than δ if α and n are sufficiently large. As for the second term, it is clearly less or equal to

$$\mathbb{P}\left(\max_{k \leq \alpha\sqrt{\lfloor nt \rfloor}} \left| \sum_{i \leq k} (1 - \tau_i) \right| > \varepsilon\sqrt{n}\right). \quad (11)$$

Observe that, by the law of large numbers, for any positive ε' and δ there exists $k_0 = k_0(\varepsilon', \delta)$ such that for all $k \geq k_0$

$$\mathbb{P}\left(\left|\frac{\sum_{i \leq k} (1 - \tau_i)}{k}\right| < \varepsilon'\right) \geq 1 - \delta.$$

Hence (11) is less or equal to

$$\mathbb{P}\left(\max_{k \leq k_0} \left|\sum_{i \leq k} (1 - \tau_i)\right| > \varepsilon\sqrt{n}\right) + \mathbb{P}\left(\max_{k_0 \leq k \leq \alpha\sqrt{[nt]}} \left|\sum_{i \leq k} (1 - \tau_i)\right| > \varepsilon\sqrt{n}\right).$$

The first term clearly tends to 0 as n grows to infinity, while the second term is not larger than

$$\delta + \mathbb{P}\left(\max_{k_0 \leq k \leq \alpha\sqrt{[nt]}} \left|\sum_{i \leq k} (1 - \tau_i)\right| > \varepsilon\sqrt{n}, \left|\frac{\sum_{i \leq k} (1 - \tau_i)}{k}\right| < \varepsilon' \quad \forall k \geq k_0\right).$$

But if $|\sum_{i \leq k} (1 - \tau_i)|/k < \varepsilon'$ for all $k \geq k_0$, then

$$\sup_{k_0 \leq k \leq \alpha\sqrt{[nt]}} \left|\sum_{i \leq k} (1 - \tau_i)\right| < \alpha\varepsilon'\sqrt{[nt]},$$

which is smaller than $\varepsilon\sqrt{n}$ if ε' is sufficiently small. This proves that $I \xrightarrow{U.P.} 0$.

We now prove that $II \xrightarrow{U.P.} 0$. Indeed

$$0 \leq L_{[ns] + \sum_{i \leq L'_{[ns]}} \tau_i} - L_{[ns]} \leq \sum_{i \leq L'_{[ns]}} \tau_i - \sum_{i \leq l_{[ns]} - 1} \tau_i = \sum_{i=l_{[ns]}}^{L'_{[ns]}} \tau_i.$$

Using (8) and the definitions of L'' and $\tilde{\tau}$ thereafter, we have that $\sum_{i=l_{[ns]}}^{L'_{[ns]}} \tau_i \leq \sum_{i=0}^{L''_{[ns]} - N_{[ns]}} \tilde{\tau}_i$, and for any positive ε' ,

$$\sup_{s \leq t} \sum_{i=0}^{L''_{[ns]} - N_{[ns]}} \tilde{\tau}_i = \max \left\{ \sup_{s \leq \varepsilon'} \sum_{i=0}^{L''_{[ns]} - N_{[ns]}} \tilde{\tau}_i, \sup_{\varepsilon' < s \leq t} \sum_{i=0}^{L''_{[ns]} - N_{[ns]}} \tilde{\tau}_i \right\} =: \max(C, D).$$

Choose $\delta > 0$. Let us show that $\mathbb{P}(C > \varepsilon\sqrt{n}) < \delta$ if ε' is sufficiently small and n sufficiently large. Indeed

$$\sup_{s \leq \varepsilon'} \sum_{i=0}^{L''_{[ns]} - N_{[ns]}} \tilde{\tau}_i \leq \sum_{i=0}^{L''_{[n\varepsilon']}} \tilde{\tau}_i,$$

and by independence of $L''_{[n\varepsilon']}$ and $\tilde{\tau}$,

$$\mathbb{P}\left(\sum_{i \leq L''_{[n\varepsilon']}} \tilde{\tau}_i > \varepsilon\sqrt{n}\right) \leq \mathbb{P}\left(L''_{[n\varepsilon']} > \alpha\sqrt{[n\varepsilon']}\right) + \mathbb{P}\left(\sum_{i \leq \alpha\sqrt{[n\varepsilon']}} \tilde{\tau}_i > \varepsilon\sqrt{n}\right). \quad (12)$$

Choose α such that $\mathbb{P}\left(L''_{\lfloor n\varepsilon' \rfloor} > \alpha\sqrt{\lfloor n\varepsilon' \rfloor}\right) < \delta$ for n sufficiently large, and then ε' sufficiently small such that $\mathbb{P}\left(\sum_{i \leq \alpha\sqrt{\lfloor n\varepsilon' \rfloor}} \tilde{\tau}_i > \varepsilon\sqrt{n}\right) < \delta$.

Now keep ε' fixed. In order to prove that $\mathbb{P}(D > \varepsilon\sqrt{n}) < 3\delta$ for n sufficiently large, we observe that for any positive ε'' there exists \bar{n} such that for all $n \geq \bar{n}$, $\mathbb{P}\left(N_n \geq n(1 - \varepsilon'')\right)$ is larger than $1 - \delta$. Then for all n such that $\lfloor n\varepsilon' \rfloor \geq \bar{n}$, $\sup_{\varepsilon' < s \leq t} \left(L''_{\lfloor ns \rfloor} - N_{\lfloor ns \rfloor}\right) \leq L''_{\lfloor nt\varepsilon'' \rfloor}$ with probability larger than $1 - \delta$. Hence, as in (12) we have that, for α and n sufficiently large and ε'' sufficiently small.

$$\begin{aligned} \mathbb{P}(D > \varepsilon\sqrt{n}) &\leq \delta + \mathbb{P}\left(\sum_{i \leq L''_{\lfloor nt\varepsilon'' \rfloor}} \tilde{\tau}_i > \varepsilon\sqrt{n}\right) \\ &\leq \delta + \mathbb{P}\left(L''_{\lfloor nt\varepsilon'' \rfloor} > \alpha\sqrt{\lfloor nt\varepsilon'' \rfloor}\right) + \mathbb{P}\left(\sum_{i \leq \alpha\sqrt{\lfloor nt\varepsilon'' \rfloor}} \tilde{\tau}_i > \varepsilon\sqrt{n}\right) < 3\delta. \end{aligned}$$

□

Proposition 6.5.

$$\left(\frac{X_{L_{nt}}}{\sqrt[4]{n}}\right)_{t \geq 0} \xrightarrow{U.P.} \left(W_{L_t^0(B)}\right)_{t \geq 0}.$$

Proof. Clearly the statement may be rephrased as

$$\left(\frac{X_{L_{n^2t}}}{\sqrt{n}}\right)_{t \geq 0} \xrightarrow{U.P.} \left(W_{L_t^0(B)}\right)_{t \geq 0}.$$

Note that (writing L_s^0 instead of $L_s^0(B)$)

$$\sup_{s \leq t} \left| \frac{X_{L_{n^2s}}}{\sqrt{n}} - W_{L_s^0} \right| \leq \sup_{s \leq t} \left| \frac{X_{L_{n^2s}} - X_{nL_s^0}}{\sqrt{n}} \right| + \sup_{s \leq t} \left| \frac{X_{nL_s^0}}{\sqrt{n}} - W_{L_s^0} \right| = (A) + (B).$$

We have to show that (A) and (B) $\xrightarrow{U.P.} 0$: it suffices to prove the statement for $L_{\lfloor n^2s \rfloor}$ and $\lfloor nL_s^0 \rfloor$ instead of L_{n^2s} and nL_s^0 respectively. Represent $X_k = \sum_{i=1}^k \tilde{\eta}_i$, where $\tilde{\eta} = \{\tilde{\eta}_i\}_{i \geq 1}$ is an iid family such that $\mathbb{P}(\tilde{\eta}_i = \pm 1) = 1/2$, then

$$\sup_{s \leq t} \left| X_{L_{\lfloor n^2s \rfloor}} - X_{\lfloor nL_s^0 \rfloor} \right| = \sup_{s \leq t} \left| \sum_{i=1}^{n\Delta_{n,s}} \eta_i \right|,$$

where $n\Delta_{n,s} := \lfloor L_{\lfloor n^2s \rfloor} \rfloor - \lfloor nL_s^0 \rfloor$ and $\eta_i = \tilde{\eta}_{\min\{\lfloor L_{\lfloor n^2s \rfloor} \rfloor, \lfloor nL_s^0 \rfloor\} + i}$. Note that $(\Delta_{n,t})_{t \geq 0} \xrightarrow{U.P.} 0$, indeed

$$\Delta_{n,t} \leq \left| \frac{L_{\lfloor n^2t \rfloor}}{n} - L_t^0 \right| + \left| L_t^0 - \frac{\lfloor nL_t^0 \rfloor}{n} \right| \leq \left| \frac{L_{\lfloor n^2t \rfloor}}{n} - L_t^0 \right| + \frac{1}{n},$$

and both these summands tends U.P. to 0 (the first by Proposition 6.4). In order to show that

$$\mathbb{P} \left(\sup_{s \leq t} \left| \sum_{i=1}^{n\Delta_{n,s}} \eta_i \right| > \varepsilon \sqrt{n} \right) \xrightarrow{n \rightarrow \infty} 0$$

it suffices to prove that

$$\mathbb{P} \left(\max_{k \leq \sup_{s \leq t} (n\Delta_{n,s})} \sum_{i=1}^k \eta_i > \varepsilon \sqrt{n} \right) \xrightarrow{n \rightarrow \infty} 0.$$

Now put $M_n = \max_{k \leq n} \sum_{i=1}^k \eta_i$ and recall that $(n\Delta_{n,s})_{n \geq 0, s \leq t}$ and η are independent: this last probability may be written as

$$\begin{aligned} & \sum_{j=0}^{\infty} \mathbb{P}(M_j > \varepsilon \sqrt{n}) \mathbb{P} \left(\sup_{s \leq t} (n\Delta_{n,s}) = j \right) \\ & \leq \mathbb{P} \left(\sup_{s \leq t} (\Delta_{n,s}) > \alpha \right) + \mathbb{P}(M_{\lfloor n\alpha \rfloor} > \varepsilon \sqrt{n}). \end{aligned}$$

For all positive α , $\mathbb{P}(\sup_{s \leq t} (\Delta_{n,s}) > \alpha)$ can be made arbitrarily small if n is picked large enough, while

$$\mathbb{P}(M_{\lfloor n\alpha \rfloor} > \varepsilon \sqrt{n}) \xrightarrow{n \rightarrow \infty} \mathbb{P} \left(|\mathcal{N}(0, 1)| > \frac{\varepsilon}{\sqrt{\alpha}} \right).$$

Thus if $\delta > 0$ is fixed, by choosing α sufficiently small we get $\mathbb{P}(M_{\lfloor n\alpha \rfloor} > \varepsilon \sqrt{n}) < \delta$ if n is sufficiently large. This proves (A) $\xrightarrow{U.P.} 0$.

Now note that X_n and L_s^0 are independent, so we may think of $X_{\lfloor nL_s^0 \rfloor}$ as defined on a product probability space $\Omega_1 \otimes \Omega_2$ (that is $X_{\lfloor nL_s^0 \rfloor}(\omega_1, \omega_2) = X_{\lfloor nL_s^0(\omega_2) \rfloor}(\omega_1)$). For any fixed ω_2 we have that

$$\mathbb{P}_1 \left(\sup_{s \leq t} \left| \frac{X_{\lfloor nL_s^0(\omega_2) \rfloor}}{\sqrt{n}} - W_{L_s^0(\omega_2)} \right| > \varepsilon \right) \xrightarrow{n \rightarrow \infty} 0. \quad (13)$$

Indeed it is known (see (5)) that $\mathbb{P}_1 \left(\sup_{s \leq t} \left| \frac{X_{ns}}{\sqrt{n}} - W_s \right| > \varepsilon \right) \xrightarrow{n \rightarrow \infty} 0$, and since for any fixed ω_2 , as $s \uparrow t$, $L_s^0(\omega_2) \uparrow L_t^0(\omega_2)$,

$$\sup_{s \leq t} \left| \frac{X_{\lfloor nL_s^0(\omega_2) \rfloor}}{\sqrt{n}} - W_{L_s^0(\omega_2)} \right| \leq \sup_{s \leq L_t^0(\omega_2)} \left| \frac{X_{\lfloor ns \rfloor}}{\sqrt{n}} - W_s \right|,$$

whence (13). Thus, putting

$$A_n := \left\{ (\omega_1, \omega_2) : \sup_{s \leq t} \left| \frac{X_{\lfloor nL_s^0(\omega_2) \rfloor}(\omega_1)}{\sqrt{n}} - W_{L_s^0(\omega_2)}(\omega_1) \right| > \varepsilon \right\},$$

we have that $\mathbb{P}_1(A_n) \rightarrow 0$, by Fubini and the dominated convergence theorem we get $\mathbb{P}_1 \otimes \mathbb{P}_2(A_n) \rightarrow 0$ and we are done. \square

7 Final remarks

The inhomogeneity of \mathbf{C}_2 results in the difference between the behaviour of the horizontal and vertical components of the walk. Indeed while for any positive integer d the expected value of the distance from the origin of the simple random walker on \mathbb{Z}^d , after n steps, is of order $n^{1/2}$ (this may be easily proven via a conditioning argument, with respect to the proportions of time spent along each of the d main directions), the expected value of the horizontal distance on \mathbf{C}_2 is of order $n^{1/4}$, that is on this direction we have a subdiffusive behaviour.

The difference between the two projections of the walk is remarkable also when one properly rescales the process as we did in Section 6. Indeed although both components scale to a Brownian motion, the horizontal one is much slower (its clock is the local time at 0 of the vertical component).

Finally, also the failure of the Einstein relation on \mathbf{C}_2 is due to the inhomogeneity of this particular graph. Indeed for strongly inhomogeneous graphs the growth exponent does not give an accurate description of the “fractal properties” of the graph (the assignment of the same δ_f of \mathbb{Z}^2 to \mathbf{C}_2 disregards the topology of the two structures). It seems that defining δ_f as the growth exponent of the graph makes sense only for homogeneous graphs (like \mathbb{Z}^d) or self-similar graphs, which have a clear fractal nature (like the Sierpiński graph). It is our opinion that the study of the sense in which a graph has a fractal nature and what is the proper definition of its fractal dimension should require further investigations.

Acknowledgments

I feel particularly indebted to Peter Grabner and Helmut Prodinger for raising the questions discussed in this paper and for the stimulating discussions during which they suggested the techniques used in Sections 3, 4 and 5. I would also like to thank Jean-Francois Le Gall for suggesting the limit of the rescaled process and giving me some precious hints.
