# THE LOWEST CROSSING IN TWO-DIMENSIONAL CRITICAL PERCOLATION 

By J. van den Berg and A. A. Járai ${ }^{1}$<br>CWI, Amsterdam and University of British Columbia, Vancouver

#### Abstract

We study the following problem for critical site percolation on the triangular lattice. Let $A$ and $B$ be sites on a horizontal line $e$ separated by distance $n$. Consider, in the half-plane above $e$, the lowest occupied crossing $R_{n}$ from the half-line left of $A$ to the half-line right of $B$. We show that the probability that $R_{n}$ has a site at distance smaller than $m$ from $A B$ is of order $(\log (n / m))^{-1}$, uniformly in $1 \leq m \leq n / 2$. Much of our analysis can be carried out for other two-dimensional lattices as well.

1. Introduction. The idea of the "lowest" crossing between two boundary pieces of a domain is a well-known and useful tool in the study of two-dimensional percolation. Here we are interested in the question of how close the lowest crossing comes to the intermediate boundary piece it has to cross. To be specific, we fix the domain to be a half-plane and the two boundary pieces to be two disjoint half-lines.
1.1. Statement of the main result. Let $\mathbb{T}$ denote the triangular lattice. We note that much of our discussion applies to other lattices as well. We consider $\mathbb{T}$ as a subset of the Euclidean plane in such a way that the distance between two neighbor vertices of $\mathbb{T}$ is 1 and the integer points on the $X$-axis $e$ are vertices of $\mathbb{T}$. For notational convenience, we denote these vertices on $e$ by $\ldots,-2,-1,0,1,2, \ldots$. Denote the site 0 by $A$ and the site $n$ by $B$. Let $l=(-\infty, A) \cap \mathbb{T}, r=(B, \infty) \cap \mathbb{T}$, and let $\mathbb{H}$ be the half-plane above (and including) $e$. Each site $v \in \mathbb{T}$ is occupied with probability $p$ and vacant with probability $1-p$, independently. The corresponding probability measure is denoted by $\operatorname{Prob}_{p}$, and expectation by $E_{p}$. If $S_{1}, S_{2}$ are sets of sites, we say that $S_{1}$ is connected to $S_{2}$, or $S_{1} \leftrightarrow S_{2}$, if there is a path of occupied sites that starts in $S_{1}$ and ends in $S_{2}$. We say that $S_{1} \leftrightarrow S_{2}$ inside $S_{3}$ if all sites of the path are in $S_{3}$.

All constants below are strictly positive and finite. We write $a_{n} \asymp b_{n}$ to denote that there are constants $C_{1}$ and $C_{2}$ such that $C_{1} a_{n} \leq b_{n} \leq C_{2} a_{n}$. The exact values of constants denoted by $C_{i}$ are not important to us, and $C_{i}$ may have a different value from place to place.

REMARK. In the remainder of this paper, "path" will always mean "selfavoiding path" (i.e., a path that does not visit the same site more than once).

[^0]The lowest crossing. Consider all occupied paths between $l$ and $r$ that stay inside $\mathbb{H}$. If there is such a path, then there is a unique one closest to $A B$, call it $R$ (we suppress the dependence of $R$ on $n$ ). [See page 317 of Grimmett (1999) and Kesten (1982) for a discussion of the lowest crossing.] If $R$ contains a site on $A B$, we call it a contact point.

We are only interested in contact points at criticality. This is because for $p<p_{c}$ the probability of an occupied crossing from $l$ to $r$ decays exponentially as $n \rightarrow \infty$. Also, it is not hard to see that for $p>p_{c}$ the fraction of those points on $A B$ that are contact points is typically bounded away from 0 . From now on, we set $p=1 / 2$, the critical probability for site percolation on $\mathbb{T}$. We write $\operatorname{Prob}_{\text {cr }}$ for $\operatorname{Prob}_{1 / 2}$. We note that by a Russo-Seymour-Welsh (RSW) argument [see Section 11.7 of Grimmett (1999), Theorem 6.1 of Kesten (1982), Russo $(1978,1981)$ and Seymour and Welsh (1978)], we have $\operatorname{Prob}_{\mathrm{cr}}(R$ exists $)=1$.

Our main result is the following theorem.
THEOREM 1. We have, uniformly in $1 \leq m \leq n / 2$,

$$
\operatorname{Prob}_{\mathrm{cr}}(R \text { has distance }<m \text { from } A B) \asymp(\log (n / m))^{-1} .
$$

This theorem immediately implies (take $m=1$ ) the following corollary.
Corollary 2.

$$
\operatorname{Prob}_{\mathrm{cr}}(R \text { has a contact point }) \asymp(\log n)^{-1}, \quad n \geq 1 .
$$

REmARKS. (i) Note that it is not even a priori obvious (and a new result in itself) that this probability goes to 0 as $n$ goes to $\infty$ [see also (iv) below].
(ii) The statement of Theorem 1 is interesting only when $m$ is small compared to $n$; when $m$ is of the same order as $n$, the result follows easily from an RSW argument.
(iii) As to the case where $m \gg n$, a simple RSW argument shows that there exists an $\varepsilon>0$ such that the probability that $R$ has distance larger than $\lambda n$ from $A B$ is smaller than $\lambda^{-\varepsilon}$, uniformly in $n$ and $\lambda>2$.
(iv) The only prerequisites needed in the proof are classical percolation results and techniques, in particular, the RSW techniques. We do not use SLE processes, which were introduced by Schramm and which have, by the work of him and other mathematicians, recently led to enormous progress [see Smirnov and Werner (2001) and the references given there]. In fact, we hope that Theorem 1 will be useful in the study of SLE $_{6}$. To illustrate this, note that Theorem 1 indicates that in the scaling limit when the lattice spacing goes to 0 and the length of $A B$ is kept fixed (say 1), the distribution of the distance of $R$ from $A B$ satisfies

$$
\operatorname{Prob}_{\mathrm{cr}}(R \text { has distance }<a \text { from } A B) \asymp(\log (1 / a))^{-1}, \quad a<1 / 2 .
$$

In the scaling limit, $R$ corresponds to the boundary of the hull of the chordal SLE $_{6}$ process in the half-plane started from 0 and stopped at the first time it hits $(1, \infty)$ [see Corollary 5 of Smirnov (2001)]. In this way, one should obtain an analog of Theorem 1 in terms of $\mathrm{SLE}_{6}$. The existence of a direct proof for $\mathrm{SLE}_{6}$ of such a result is not known to us. Werner (private communication) has informed us that a (quite convoluted) "direct" proof of a weaker form of such a result for SLE $_{6}$ [namely, that the distance between the boundary of the hull and the interval $(0,1)$ is a.s. strictly positive] will be included (among other results) in a joint paper by him, Lawler and Schramm.
(v) Schramm (2000) has proved that, for uniform spanning trees, the analog of the left-hand side of our Theorem 1 goes to 0 as $m / n$ goes to 0 , uniformly in $n$. Schramm (private communication) informed us recently that for that model the more precise behavior we obtained for percolation [i.e., the $(\log (n / m))^{-1}$ order] also seems to hold.

Apart from the above considerations, we think that Theorem 1 is interesting in itself.
1.2. Notation, definitions and key ingredients. The theorem follows from the proposition below. This proposition uses the knowledge of the critical exponent describing the scaling of the probability that there are two disjoint occupied paths in $\mathbb{H}$ that start at 0 and end at distance $n$. First, we give some additional definitions and notation.

For $n \geq 1$ and $v \in A B$, define the set

$$
H_{n}(v)=\{u \in \mathbb{H}:|u-v|<n\},
$$

where $|\cdot|$ is the graph distance from the origin. We are also going to need the half-annulus

$$
H_{n, m}(v) \stackrel{\text { def }}{=} H_{n}(v) \backslash H_{m}(v)=\{u \in \mathbb{H}: m \leq|u-v|<n\} .
$$

If $S$ is a set of sites, we set
$\partial S=$ the set of sites in $S$ that have a neighbor in $S^{c} \cap \mathbb{H}$
and
$\bar{\partial} S=$ the set of sites in $S^{c} \cap \mathbb{H}$ that have a neighbor in $S$.
We define the event

$$
D_{n}(v)=\left\{\exists \text { two disjoint occupied paths from } \bar{\partial}\{v\} \text { to } \partial H_{n}(v)\right\} .
$$

Here, and later, "disjoint" means "vertex disjoint." We set

$$
\rho(n)=\operatorname{Prob}_{\mathrm{cr}}\left(D_{n}(0)\right) .
$$

It is clear that this quantity will be important in our analysis: for a site $v \in A B$ to be a contact point, there must be two disjoint occupied paths from $\bar{\partial}\{v\}$ to the sets $l$ and $r$, respectively; when $v$ is in the bulk of $A B$, both sets have distance of order $n$ from $v$.

We also need a version of $D_{n}$ for $H_{n, m}(v)$. For $1 \leq m<n$, let

$$
\begin{aligned}
D_{n, m}(v) & =\left\{\exists \text { two disjoint occupied paths from } \bar{\partial} H_{m}(v) \text { to } \partial H_{n}(v)\right\}, \\
\rho(n, m) & =\operatorname{Prob}_{\mathrm{cr}}\left(D_{n, m}(0)\right) .
\end{aligned}
$$

We are going to need the following lemma about $\rho$. This lemma concerns the socalled "two-arm half-plane exponent." This exponent is exceptional in the sense that it can be derived in a quite elementary way, only using RSW, FKG and symmetry (the self-matching property of site percolation on the triangular lattice). It seems that this has been "known" for a while [see, e.g., the remark in Aizenman, Duplantier and Aharony (1999) that this exponent is "directly derivable"], but until recently there was (as far as we know) no explicit proof in the literature, although quite similar observations were made by Kesten, Sidoravicius and Zhang (1998) and Zhang (1999). Lawler, Schramm and Werner (2002), who needed such a lemma to bridge a step in the much more involved computation of other critical exponents, have included a proof in Appendix A of their paper.

LEMMA 3. (i) $\rho(n) \asymp n^{-1}, n>1$;
(ii) $\rho(n, m) \asymp(n / m)^{-1}$, uniformly in $1 \leq m<n$.

Finally, we state the following proposition. First, let

$$
X_{n, m}=\mid\left\{0 \leq k \leq n / m: H_{m}(k m) \text { is visited by } R\right\} \mid, \quad 1 \leq m \leq n / 2 .
$$

Proposition 4. Uniformly in $1 \leq m \leq n / 2$, with $n$ a multiple of $m$, we have:
(i) $E_{\text {cr }} X_{n, m} \asymp 1$;
(ii) $E_{\text {cr }}\left(X_{n, m} \mid X_{n, m} \geq 1\right) \asymp \log (n / m)$;
(iii) $E_{\mathrm{cr}} X_{n, m}^{2} \asymp \log (n / m)$;
(iv) $\operatorname{Prob}_{\text {cr }}\left(X_{n, m} \geq 1\right) \asymp(\log (n / m))^{-1}$.
1.3. Outline. The rest of the paper is organized as follows. In Section 2.1, we prove Proposition 4 from which, as we will see in Section 2.2, Theorem 1 follows immediately. The only part that uses the lattice structure in an essential way is the proof of the lemma. The rest can easily be modified to suit other two-dimensional lattices.
2. Proofs. We will make frequent use of the event defined below. We call a path $\pi$ in the half-annulus $H_{n, m}(v)$ a half-circuit if it connects the two boundary pieces of $H_{n, m}(v)$ lying on the boundary of $\mathbb{H}$. Let

$$
F_{n, m}(v)=\left\{\exists \text { occupied half-circuit in } H_{n, m}(v)\right\} .
$$

2.1. Proof of Proposition 4. Let $R, A$ and $B$ be as in Section 1 and let $1 \leq m \leq n / 2$ with $n$ a multiple of $m$. Observe that for $k m \in A B$ we have

$$
\begin{align*}
& \mathrm{R} \text { visits } H_{m}(\mathrm{~km}) \quad \text { if and only if } \\
& \exists \text { occupied path from } l \text { to } r \text { that visits } H_{m}(\mathrm{~km}), \tag{1}
\end{align*}
$$

and define the events

$$
\begin{aligned}
A_{k, n, m} & =\left\{\exists \text { occupied path from } l \text { to } r \text { that visits } H_{m}(k m)\right\} \\
& =\left\{R \text { visits } H_{m}(k m)\right\}, \quad 0 \leq k \leq n / m .
\end{aligned}
$$

Since in what follows $n$ and $m$ are fixed, we simply write $A_{k}$ for $A_{k, n, m}$. We can write

$$
X_{n, m}=\sum_{0 \leq k \leq n / m} I\left[A_{k}\right],
$$

where $I[\cdot]$ denotes the indicator of an event.
Throughout the proof, we will assume that $m \geq 2$. The proof for $m=1$ is similar and, in part (ii), simpler.

Proof of (i). We start with a lower bound for $E_{\text {cr }} X_{n, m}$. By inclusion of events (see Figure 1) and the FKG inequality, we have

$$
\begin{align*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{k}\right) & \geq \operatorname{Prob}_{\mathrm{cr}}\left(F_{2 n, n}(k m) \cap D_{2 n, m / 2}(k m) \cap F_{m, m / 2}(k m)\right) \\
& \geq \operatorname{Prob}_{\mathrm{cr}}\left(F_{2 n, n}(k m)\right) \rho(2 n, m / 2) \operatorname{Prob}_{\mathrm{cr}}\left(F_{m, m / 2}(k m)\right) \tag{2}
\end{align*}
$$

for any integer $k \in[0, n / m]$. Here and later, fractions are meant to be replaced by their integer parts whenever necessary. By an RSW argument, the first and third factors are bounded below by some constant $C_{1}$. Therefore, by Lemma 3, we have

$$
E_{\mathrm{cr}} X_{n, m}=\sum_{0 \leq k \leq n / m} \operatorname{Prob}_{\mathrm{cr}}\left(A_{k}\right) \geq C_{1}^{2} C_{2}(n / m)(n / m)^{-1}=C_{1}^{2} C_{2}
$$

For the upper bound, we introduce the event

$$
G_{n, m}(v)=\left\{\exists \text { occupied path from } \bar{\partial} H_{m}(v) \text { to } \partial H_{n}(v)\right\}, \quad 1 \leq m<n .
$$

The scaling of $\operatorname{Prob}_{\mathrm{cr}}\left(G_{n, m}\right)$ is known for the triangular lattice [see Theorem 3 of Smirnov and Werner (2001)]. However, for an argument valid on general lattices, we only use a power law upper bound. An RSW argument [in fact, a simple modification of Theorem 11.89 of Grimmett (1999)] shows that

$$
\begin{equation*}
\operatorname{Prob}_{\mathrm{cr}}\left(G_{n, m}\right) \leq C_{3}(n / m)^{-\mu} \tag{3}
\end{equation*}
$$

FIG. 1. The events that force the occurrence of $A_{k}$.
for some positive constants $\mu$ and $C_{3}$.
Let $1 \leq k \leq \frac{1}{2}(n / m)$ and assume that the event $A_{k}$ occurs. Then it is easy to see that the events $D_{k m, m}(\mathrm{~km})$ and $G_{n / 2, k m}(\mathrm{~km})$ both occur. Since these latter events are independent, we have, by Lemma 3 and (3),

$$
\operatorname{Prob}_{\mathrm{cr}}\left(A_{k}\right) \leq \operatorname{Prob} \mathrm{cr}\left(D_{k m, m}(k m)\right) \operatorname{Prob}_{\mathrm{cr}}\left(G_{n / 2, k m}(k m)\right) \leq C_{4} \frac{1}{k}\left(\frac{k m}{n}\right)^{\mu} .
$$

The sum of the right-hand side over these $k$ 's is bounded by some constant $C_{5}$ independent of $n$ and $m$. A similar argument applies when $\frac{1}{2}(n / m)<k \leq(n / m)-1$. Finally, in the case $k=0$ or $k=n / m$, we have $\operatorname{Prob}_{\text {cr }}\left(A_{k}\right) \leq 1$. This proves that $E_{\mathrm{cr}} X_{n, m} \leq C_{6}$.

PROOF OF THE LOWER BOUND IN PART (ii). The idea in this proof is, roughly speaking, as follows: if $A_{k}$ occurs, there are from $H_{m}(\mathrm{~km})$ disjoint occupied paths to $l$ and $r$, respectively. Hence, to "let also $A_{j}$ occur," it (almost) suffices to have two disjoint occupied paths from $H_{m}(j m)$ to the latter path, and this should, by RSW arguments, "cost" a probability of order $\operatorname{Prob}_{\mathrm{cr}}\left(D_{(j-k) m, m}(j m)\right)$, which by the lemma is of order $1 /(j-k)$. However, if one does the conditioning in a naive way, technical difficulties arise because "negative information can seep through." Therefore, the argument has to be done very carefully and an auxiliary event (which we will call $F_{k}^{*}$ below) has to be introduced to "neutralize" this negative information. We now give the precise arguments.

Let $V$ denote the first intersection of $R$ with the set

$$
U=\bigcup_{0 \leq k \leq n / m} H_{m}(k m),
$$

if such an intersection exists when $R$ is traversed from left to right. For $v \in \partial U$, let $B_{v}=\{V=v\}$ and define $k$ to be the index for which $v \in H_{m}(k m)$, choosing the smaller if there are two of them. We prove the lower bound

$$
\begin{equation*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{j} \mid B_{v}\right) \geq \frac{C_{1}}{j-k} \quad \text { for } k+4 \leq j \leq n / m-1,1 \leq k \leq n /(2 m) \tag{4}
\end{equation*}
$$

Let
$R_{1}=$ the piece of $R$ to the left of $V$, including the site $V$.
Also, define

$$
\begin{align*}
S_{1}(v)= & \text { the lowest occupied path from } l \text { to } v \text { that is disjoint from } U, \\
& \text { apart from the site } v, \tag{5}
\end{align*}
$$

whenever there is at least one such path. Note that even when the event $B_{v}$ does not hold, such paths may exist. We claim that on the event $B_{v}$ we have $R_{1}=S_{1}(v)$. Since $V=v$, we have that $R_{1}$ is disjoint from $U$, apart from $v$. If $S_{1}(v)$ were lower than $R_{1}$, then we would use $S_{1}(v)$ and the piece of $R$ to the right of $v$ to construct an occupied crossing lower than $R$, a contradiction.

For a path $\pi$, we write $\left\{S_{1}(v)=\pi\right\}$ as a shorthand for the event that $S_{1}(v)$ exists, and $S_{1}(v)=\pi$. The proof of the lower bound in (ii) is based on the following observation:

$$
\begin{equation*}
B_{v}=\bigcup_{\pi_{1}}\left\{S_{1}(v)=\pi_{1}\right\} \cap \Theta\left(\pi_{1}, v\right) \cap \Delta\left(\pi_{1}, v\right) \tag{6}
\end{equation*}
$$

where

$$
\begin{aligned}
& \Theta\left(\pi_{1}, v\right)=\left\{\begin{array}{l}
\exists \text { vacant path } \pi_{2}^{*} \text { from } \bar{\partial}\{v\} \text { to } A B \text { s.t. } \pi_{1} \text { is } \\
\text { the occupied path from } l \text { to } v \text { closest to } \pi_{2}^{*}
\end{array}\right\}, \\
& \Delta\left(\pi_{1}, v\right)=\left\{\exists \text { occupied path } \pi_{3} \text { from } \bar{\partial}\{v\} \text { to } r \text { disjoint from } \pi_{1}\right\},
\end{aligned}
$$

and where the union is over all paths $\pi_{1}$ from $l$ to $v$ that are disjoint from $U$, apart from the site $v$. We will, for the time being, consider $v$ as fixed, and, to simplify notation, write $S_{1}, \Theta\left(\pi_{1}\right)$ and $\Delta\left(\pi_{1}\right)$ instead of $S_{1}(v)$, and so on.

We first show that if $B_{v}$ occurs, then the right-hand side of (6) occurs. Take $\pi_{1}=R_{1}$. Then by the discussion following (5) the event $\left\{S_{1}=\pi_{1}\right\}$ occurs. Since $R$ is the lowest crossing, there is a vacant path from $\bar{\partial}\{v\}$ to $A B$. Take $\pi_{2}^{*}$ to be the one closest to $\pi_{1}$. We claim that then $\pi_{1}$ is also the occupied path closest to $\pi_{2}^{*}$. Let $\rho$ be an occupied path from $l$ to $v$ that is closer to $\pi_{2}^{*}$ than $\pi_{1}$. Since $\pi_{2}^{*}$ is below $R, \rho$ is also below $R$. Now $\rho$ together with the piece of $R$ to the right of $v$ forms an occupied crossing lower than $R$, a contradiction. This shows that $\Theta\left(\pi_{1}\right)$ occurs. Finally, taking $\pi_{3}$ to be the piece of $R$ to the right of $v$ shows that $\Delta\left(\pi_{1}\right)$ occurs.

Next, assume that the right-hand side of (6) occurs and choose the paths $\pi_{1}$, $\pi_{2}^{*}$ and $\pi_{3}$ that show this. The fact that $\pi_{1}, \pi_{3}$ are occupied and that $\pi_{2}^{*}$ is vacant implies that $R$ exists and passes through $v$. Thus, $R_{1}$, the piece of $R$ to the left of $v$, is defined. Also, $R$ lies below the concatenation of $\pi_{1}$ and $\pi_{3}$. Since $\pi_{2}^{*}$ is vacant, $R_{1}$ lies between $\pi_{1}$ and $\pi_{2}^{*}$. Since $\Theta\left(\pi_{1}\right)$ occurs, $R_{1}=\pi_{1}=S_{1}$, and hence $v$ is the first intersection of $R$ with $U$, that is, $B_{v}$ occurs.

Now we are ready to start the argument for (4). By (6), we can write

$$
\begin{equation*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{j} \cap B_{v}\right)=\sum_{\pi_{1}} \operatorname{Prob}_{\mathrm{cr}}\left(\left\{S_{1}=\pi_{1}\right\} \cap \Theta\left(\pi_{1}\right) \cap \Delta\left(\pi_{1}\right) \cap A_{j}\right) . \tag{7}
\end{equation*}
$$

Fix $\pi_{1}$ and on the event $\Delta\left(\pi_{1}\right)$ let $S_{3}\left(\pi_{1}\right)$ denote the highest occupied path from $\bar{\partial}\{v\}$ to $r$ disjoint from $\pi_{1}$. The occurrence of the event $\left\{S_{1}=\pi_{1}\right\}$ only depends on the states of $v$ and the sites that are on or below $\pi_{1}$ but outside $U$. Let $\Omega\left(\pi_{1}\right)$ denote this set. For fixed $\pi_{1}$, the occurrence of $\left\{S_{3}\left(\pi_{1}\right)=\pi_{3}\right\}$ only depends on sites above the union of $\pi_{1}$ and $\pi_{3}$ and on the sites on $\pi_{3}$. Let $\Omega\left(\pi_{1}, \pi_{3}\right)$ denote this set. [It may happen, but is not harmful, that $\Omega\left(\pi_{1}\right) \cap \Omega\left(\pi_{1}, \pi_{3}\right) \neq \varnothing$.] We have

$$
\Delta\left(\pi_{1}\right)=\bigcup_{\pi_{3}}\left\{S_{3}\left(\pi_{1}\right)=\pi_{3}\right\}
$$

Thus, we can write

$$
\begin{equation*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{j} \cap B_{v}\right)=\sum_{\pi_{1}} \sum_{\pi_{3}} \operatorname{Prob}_{\mathrm{cr}}\left(\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right) \cap A_{j}\right) . \tag{8}
\end{equation*}
$$

Now we construct events $K_{k, j}$ and $F_{k}^{*}$ such that the events $K_{k, j}$ and $\left\{S_{1}=\pi_{1}\right.$, $\left.S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right)$ are conditionally independent given $F_{k}^{*}$, and moreover (on the event $B_{v}$ ) $K_{k, j}$ forces the occurrence of $A_{j}$. Let $\omega$ denote the configuration of occupied and vacant sites in $\mathbb{H}$ and define the configuration $\omega^{\prime}$ by setting it equal to a new independent configuration on $\Omega\left(\pi_{1}\right) \cup \Omega\left(\pi_{1}, \pi_{3}\right)$ and equal to $\omega$ on $\mathbb{H} \backslash\left(\Omega\left(\pi_{1}\right) \cup \Omega\left(\pi_{1}, \pi_{3}\right)\right)$. We let

$$
F_{k}^{*}=\left\{\text { on } \omega^{\prime} \exists \text { vacant half-circuit in } H_{2 m, m}(k m)\right\} .
$$

If $F_{k}^{*}$ occurs, then there is, in the configuration $\omega$, a vacant path $\pi_{4}^{*}$ between $A B$ and $\pi_{3}$ creating a block. This means that
the path $\pi_{2}^{*}$ in the definition of $\Theta\left(\pi_{1}\right)$ can be chosen to lie on the left-hand side of $\pi_{4}^{*}$.
Next, we define $K_{k, j}$ as the event that each of the following four occurs on $\omega^{\prime}$ :

- $\exists$ two disjoint occupied paths from $\bar{\partial} H_{m / 2}(j m)$ to $\partial H_{4(j-k+2) m}(j m)$ that avoid the set $H_{2 m}(k m)$;
- $F_{4(j-k+2) m, 2(j-k+2) m}(j m)$;
- $F_{2(j-k+2) m,(j-k+2) m}(j m)$;
- $F_{m, m / 2}(j m)$.

We note that the first event we require is "almost" $D_{4(j-k+2) m, m / 2}(j m)$. The only difference between these two events is the avoidance condition, and it is easy to see that their probabilities differ at most a constant factor. Observe that if $K_{k, j}$ occurs, then there is a path $\pi_{5}$ that is occupied on $\omega^{\prime}$, visits $H_{m}(j m)$ and has both endpoints to the left of $H_{m}(k m)$ on the boundary of $\mathbb{H}$. Let $u$ be a site on $\pi_{5}$ that is in $H_{m}(j m)$. If $u$ is above the union of $\pi_{1}$ and $\pi_{3}$, then $\pi_{3}$ visits $H_{m}(j m)$.

Fig. 2. The dashed and dotted lines represent the event $K_{k, j}$ that forces the occurrence of $A_{j}$, given $B_{v}$. We used the dashed parts to construct a path that visits $H_{m}(j m)$.

Otherwise, there are points $u^{\prime}, u^{\prime \prime} \in \pi_{5} \cap \pi_{3}$ separated by $u$, which implies that there is an occupied path (on $\omega$ ) from $\bar{\partial}\{v\}$ to $r$ that visits $H_{m}(j m)$ (see Figure 2). Thus, in both cases, $A_{j}$ occurs.

By this observation and (8), we have

$$
\begin{align*}
& \operatorname{Prob}_{\mathrm{cr}}\left(A_{j} \cap B_{v}\right) \\
& \quad \geq \sum_{\pi_{1}} \sum_{\pi_{3}} \operatorname{Prob}_{\mathrm{cr}}\left(\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right) \cap F_{k}^{*} \cap K_{k, j}\right) . \tag{10}
\end{align*}
$$

By (9) and the construction of $K_{k, j}$, it follows that, given $F_{k}^{*}, K_{k, j}$ is conditionally independent of $\Theta\left(\pi_{1}\right) \cap\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\}$. Moreover, $K_{k, j}$ is independent of $F_{k}^{*}$.

This gives that the right-hand side of (10) equals

$$
\begin{equation*}
\sum_{\pi_{1}} \sum_{\pi_{3}} \operatorname{Prob}_{\mathrm{cr}}\left(\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right) \cap F_{k}^{*}\right) \operatorname{Prob}_{\mathrm{cr}}\left(K_{k, j}\right) . \tag{11}
\end{equation*}
$$

By the FKG inequality, Lemma 3 and RSW arguments, we have

$$
\begin{equation*}
\operatorname{Prob}_{\mathrm{cr}}\left(K_{k, j}\right) \geq C_{2} \rho(4(j-k+2) m, m) \geq \frac{C_{3}}{j-k} \tag{12}
\end{equation*}
$$

To deal with the rest of the expression on the right-hand side of (11), we condition on the configuration $\sigma$ in $\Omega\left(\pi_{1}\right) \cup \Omega\left(\pi_{1}, \pi_{3}\right)$. Note that, for fixed $\pi_{1}, \pi_{3}$ and $\sigma$, the events $\Theta\left(\pi_{1}\right)$ and $F_{k}^{*}$ are decreasing in the site variables in $\mathbb{H} \backslash\left(\Omega\left(\pi_{1}\right) \cup\right.$ $\left.\Omega\left(\pi_{1}, \pi_{3}\right)\right)$. Thus, the FKG inequality implies that

$$
\begin{align*}
& \operatorname{Prob}_{\mathrm{cr}}\left(\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right) \cap F_{k}^{*}\right) \\
& \quad \geq \operatorname{Prob}_{\mathrm{cr}}\left(\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right)\right) \operatorname{Prob}_{\mathrm{cr}}\left(F_{k}^{*}\right)  \tag{13}\\
& \quad \geq C_{4} \operatorname{Prob} \operatorname{cr}\left(\left\{S_{1}=\pi_{1}, S_{3}\left(\pi_{1}\right)=\pi_{3}\right\} \cap \Theta\left(\pi_{1}\right)\right) .
\end{align*}
$$

The bounds (10)-(13) [and (6)] yield

$$
\begin{aligned}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{j} \cap B_{v}\right) & \geq \frac{C_{3} C_{4}}{j-k} \sum_{\pi_{1}, \pi_{3}} \operatorname{Prob} \\
& =\frac{C_{3} C_{4}}{j-k} \operatorname{Prob} \\
\mathrm{cr} & \left(B_{v}\right)
\end{aligned}
$$

Summing over $j$ gives, for $v$ having $x$-coordinate at most $n / 2$,

$$
\begin{equation*}
E_{\mathrm{cr}}\left(X_{n, m} \mid B_{v}\right) \geq C_{3} \log (n / m) \tag{14}
\end{equation*}
$$

Let

$$
J=\{V \text { has } x \text {-coordinate } \leq n / 2\}=\bigcup_{v: v_{x} \leq n / 2} B_{v}
$$

where the union is over all $v \in \partial U$ with $x$-coordinate at most $n / 2$. By symmetry, $\operatorname{Prob}_{\text {cr }}(J) \geq \frac{1}{2} \operatorname{Prob}_{\text {cr }}\left(X_{n, m} \geq 1\right)$. This and (14) give

$$
\begin{aligned}
E_{\mathrm{cr}}\left(X_{n, m} \mid X_{n, m} \geq 1\right) & =\frac{E_{\mathrm{cr}}\left(X_{n, m} ; X_{n, m} \geq 1\right)}{\operatorname{Prob}} \\
& \geq \frac{E_{\mathrm{cr}}\left(X_{n, m} ; J\right)}{2 \operatorname{Prob}_{\mathrm{cr}}(J)} \\
& =\frac{1}{2} E_{\mathrm{cr}}\left(X_{n, m} \mid J\right) \geq \frac{C_{3}}{2} \log \left(\frac{n}{m}\right)
\end{aligned}
$$

PROOF OF THE UPPER BOUND IN (iii). In bounding $\operatorname{Prob}_{\text {cr }}\left(A_{k} \cap A_{j}\right)$, we may assume, by symmetry, that $k \leq j$ and $k \leq n / m-j$. We may further assume that $1 \leq k \leq j-3$ by bounding $\operatorname{Prob}_{\text {cr }}\left(A_{k} \cap A_{j}\right)$ by $\operatorname{Prob}_{\mathrm{cr}}\left(A_{j}\right)$ in the cases $k=0, j-2, j-1, j$ and using (i). We separate three cases.

Case $1[j-k<2 k]$. Let $s=\lfloor(j-k-1) / 2\rfloor$ and $s^{\prime}=\lfloor(j-k) / 2\rfloor$. (We have $s^{\prime}=s$ if $j-k$ is odd, and $s^{\prime}=s+1$ if $j-k$ is even.) It is a simple matter to check the inequalities $j-k \leq k+s^{\prime} \leq n /(2 m)$. It is not difficult to see that if $A_{k} \cap A_{j}$ occurs, then the following four events occur:

$$
\begin{gathered}
D_{s m, m}(k m), \quad D_{s m, m}(j m), \quad D_{\left(k+s^{\prime}\right) m,(j-k) m}\left(\left(k+s^{\prime}\right) m\right), \\
G_{n / 2,\left(k+s^{\prime}\right) m}\left(\left(k+s^{\prime}\right) m\right) .
\end{gathered}
$$

Also note that these events are independent. Thus, by Lemma 3 and (3),

$$
\begin{align*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{k} \cap A_{j}\right) & \leq C_{1} \frac{1}{s^{2}} \frac{j-k}{k+s^{\prime}}\left(\frac{\left(k+s^{\prime}\right) m}{n / 2}\right)^{\mu} \\
& \leq C_{2} \frac{1}{(j-k)^{2}} \frac{j-k}{k}\left(\frac{k m}{n}\right)^{\mu}  \tag{15}\\
& =C_{2}(j-k)^{-1} k^{\mu-1}\left(\frac{n}{m}\right)^{-\mu}
\end{align*}
$$

where at the second inequality we used $k \leq k+s^{\prime} \leq 2 k$. The sum of the righthand side of $(15)$ over $j$ is bounded by $C_{3}(\log k) k^{\mu-1}(n / m)^{-\mu}$. The sum of this quantity over $k$ is bounded by $C_{4}(\log (n / m))(n / m)^{\mu}(n / m)^{-\mu}=C_{4} \log (n / m)$.

Case $2[2 k \leq j-k \leq 2(n / m-k) / 3]$. Define $s$ and $s^{\prime}$ as in Case 1. It is simple to check that $k \leq s^{\prime}$ and $k+s^{\prime}+(j-k) \leq n / m$. In this case, $A_{k} \cap A_{j}$ implies that the following independent events occur:

$$
D_{k m, m}(k m), \quad G_{s^{\prime} m, k m}(k m), \quad D_{s m, m}(j m), \quad G_{n-\left(k+s^{\prime}\right) m,(j-k) m}\left(\left(k+s^{\prime}\right) m\right)
$$

Thus, we have

$$
\begin{align*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{k} \cap A_{j}\right) & \leq C_{5} \frac{1}{k}\left(\frac{k}{s^{\prime}}\right)^{\mu} \frac{1}{s}\left(\frac{j-k}{n / m-k-s^{\prime}}\right)^{\mu} \\
& \leq C_{6} \frac{1}{k}\left(\frac{k}{j-k}\right)^{\mu} \frac{1}{j-k}\left(\frac{j-k}{n / m}\right)^{\mu}  \tag{16}\\
& \leq C_{6} k^{\mu-1}(j-k)^{-1}\left(\frac{n}{m}\right)^{-\mu}
\end{align*}
$$

where in the second step we used that $n / m-k-s^{\prime} \geq n /(2 m)$. The sum of the right-hand side over $j$ is bounded by $C_{7}(\log (n / m)) k^{\mu-1}(n / m)^{-\mu}$. The sum of this expression over $k$ is bounded by $C_{8}(\log (n / m))(n / m)^{\mu}(n / m)^{-\mu}=C_{8} \log (n / m)$.

Case $3[j-k>2(n / m-k) / 3]$. Our condition implies that (with $s$ and $s^{\prime}$ as before) $k \leq n / m-j<(j-k) / 2$; hence, $k \leq n / m-j \leq s$. This time $A_{k} \cap A_{j}$ implies the following independent events:

$$
D_{k m, m}(k m), \quad G_{s m, k m}(k m), \quad D_{(n / m-j) m, m}(j m), \quad G_{s m,(n / m-j) m}(j m) .
$$

This gives the bound

$$
\begin{align*}
\operatorname{Prob}_{\mathrm{cr}}\left(A_{k} \cap A_{j}\right) & \leq C_{9} \frac{1}{k}\left(\frac{k}{s}\right)^{\mu} \frac{1}{n / m-j}\left(\frac{n / m-j}{s}\right)^{\mu} \\
& \leq C_{10} \frac{1}{k}\left(\frac{k}{n / m}\right)^{\mu} \frac{1}{n / m-j}\left(\frac{n / m-j}{n / m}\right)^{\mu}  \tag{17}\\
& \leq C_{10} k^{\mu-1}(n / m-j)^{\mu-1}(n / m)^{-2 \mu}
\end{align*}
$$

where at the second inequality we used that $s \geq(j-k-2) / 2>(n / 4 m)-1$. The sum of the right-hand side of (17) over $j$ and $k$ is bounded by some $C_{11}$.

The three cases and the remark about symmetry show that

$$
E_{\mathrm{cr}} X_{n, m}^{2}=\sum_{0 \leq j, k \leq n / m} \operatorname{Prob}_{\mathrm{cr}}\left(A_{k} \cap A_{j}\right) \leq C_{12} \log (n / m)
$$

Proof of (iv). From (i) and the lower bound in (ii), we get

$$
\begin{equation*}
\operatorname{Prob}_{\mathrm{cr}}\left(X_{n, m} \geq 1\right)=\frac{E_{\mathrm{cr}} X_{n, m}}{E_{\mathrm{cr}}\left(X_{n, m} \mid X_{n, m} \geq 1\right)} \leq \frac{C_{1}}{C_{2} \log (n / m)} \tag{18}
\end{equation*}
$$

On the other hand, by the Cauchy-Schwarz inequality,

$$
\begin{equation*}
E_{\mathrm{cr}}\left(X_{n, m}\right)=E_{\mathrm{cr}}\left(X_{n, m} I\left[X_{n, m} \geq 1\right]\right) \leq\left(E_{\mathrm{cr}} X_{n, m}^{2}\right)^{1 / 2}\left(\operatorname{Prob}_{\mathrm{cr}}\left(X_{n, m} \geq 1\right)\right)^{1 / 2} \tag{19}
\end{equation*}
$$

The upper bounds in (iii) and (i) imply $\operatorname{Prob}_{\text {cr }}\left(X_{n, m} \geq 1\right) \geq C_{3}(\log (n / m))^{-1}$.

PROOF OF THE UPPER BOUND IN (ii). The equalities in (18) and (i) and (iv) now give the upper bound in (ii).

PROOF OF THE LOWER BOUND IN (iii). Similarly, (19) and (i) and (iv) give the lower bound in (iii).
2.2. Proof of Theorem 1. The case where $n$ is a multiple of $m$ is (by the definition of $X_{n, m}$ ) clearly equivalent to part (iv) of Proposition 4. As to the general case, denote the probability in the statement of the theorem by $f(n, m)$. It is easy to see, using a simple RSW argument, that if $n^{\prime}<n<n^{\prime}+m$, then $f\left(n^{\prime}, m\right)$ and $f(n, m)$ differ at most a factor $C>0$ which does not depend on $n, n^{\prime}$ and $m$. This observation, together with the special case, gives the general case.

Acknowledgments. We thank Oded Schramm for stimulating remarks that suggested to us that our result could be interesting for SLE, and Bálint Tóth for a comment that led us to consider the present, quite general, form of Theorem 1. The second author also thanks CWI for its hospitality during the summer of 2000.
