The concept of  $\lambda$ -statistical convergence for sequences of real numbers was introduced in Mursaleen (2000). In this paper, we prove decomposition theorem for  $\lambda$ -statistical convergence. We also define and study  $\lambda$ -statistical convergence,  $\lambda$ -statistically Cauchy, and strongly  $\lambda_p$ -summability in Paranormed Space.

## 1. Introduction

The notion of statistical convergence was first introduced by Fast [1]. In the recent years, statistical summability became one of the most active areas of research in summability theory, which was further generalized as lacunary statistical convergence [2],  $\lambda$ -statal convergence [3], statistical  $A$ -summability [4], and statistical  $\sigma$ -convergence [5]. Maddox [6] studied this notion in locally convex Hausdorff topological spaces and Kolk [7] defined and studied this notion in Banach spaces while Çakalli [8] extended it to topological Hausdorff groups. The concept of statistical convergence is studied in probabilistic normed space and in intuitionistic fuzzy normed spaces in [9, 10]. Recently, the statistical convergence has been studied in Paranormed Space and locally solid Riesz spaces in [11, 12], respectively. Therefore, one can choose either some different setup to study these concepts or generalizing the existing concepts through different means. In this paper, we will study the concept of  $\lambda$ -statistical convergence,  $\lambda$ -statistical Cauchy, and strongly  $\lambda_p$ -summability in Paranormed Space.

A *paranorm* is a function  $g : X \rightarrow \mathbb{R}$  defined on a linear space  $X$  such that for all  $x, y, z \in X$

$$(P1) \quad g(x) = 0 \text{ if } x = \theta,$$

$$(P2) \quad g(-x) = g(x),$$

$$(P3) \quad g(x + y) \leq g(x) + g(y),$$

(P4) if  $(\alpha_n)$  is a sequence of scalars with  $\alpha_n \rightarrow \alpha_0$  ( $n \rightarrow \infty$ ) and  $x_n, a \in X$  with  $x_n \rightarrow a$  ( $n \rightarrow \infty$ ) in the sense that  $g(x_n - a) \rightarrow 0$  ( $n \rightarrow \infty$ ), then  $\alpha_n x_n \rightarrow \alpha_0 a$  ( $n \rightarrow \infty$ ), in the sense that  $g(\alpha_n x_n - \alpha_0 a) \rightarrow 0$  ( $n \rightarrow \infty$ ).

A paranorm  $g$  for which  $g(x) = 0$  implies that  $x = \theta$  is called a *total paranorm* on  $X$ , and the pair  $(X, g)$  is called a *total Paranormed Space*.

## 2. $\lambda$ -Statistical Convergence

Let  $\lambda = (\lambda_n)$  be a nondecreasing sequence of positive numbers tending to  $\infty$  such that

$$\lambda_{n+1} \leq \lambda_n + 1, \quad \lambda_1 = 0. \quad (1)$$

The generalized de la Vallée-Poussin mean is defined by

$$t_n(x) =: \frac{1}{\lambda_n} \sum_{j \in I_n} x_j, \quad (2)$$

where  $I_n = [n - \lambda_n + 1, n]$ .

A sequence  $x = (x_j)$  is said to be  $(V, \lambda)$ -summable to a number  $L$  if

$$t_n(x) \rightarrow L \quad \text{as } n \rightarrow \infty. \quad (3)$$

Let  $K$  be a subset of the set of natural numbers  $\mathbb{N}$ . Then, the  $\lambda$ -density of  $K$  is defined as

$$\delta_\lambda(K) = \lim_n \frac{1}{\lambda_n} |\{n - \lambda_n + 1 \leq j \leq n : j \in K\}|. \quad (4)$$

The number sequence  $x = (x_j)$  is said to be  $\lambda$ -statistically convergent to the number  $L$  (c.f. [3, 13, 14]) if  $\delta_\lambda(K(\epsilon)) = 0$ ; that is, if for each  $\epsilon > 0$ ,

$$\lim_n \frac{1}{\lambda_n} |\{k \in I_n : |x_k - L| \geq \epsilon\}| = 0. \quad (5)$$

In this case we write  $\text{st}_\lambda\text{-}\lim_k x_k = L$  and we denote the set of all  $\lambda$ -statistically convergent sequences by  $S_\lambda$ . In case  $\lambda_n = n$ ,  $\lambda$ -density reduces to the natural density and  $\lambda$ -statistical convergence reduces to statistical convergence. This notion for double sequences has been studied in [15].

A sequence  $x = (x_k)$  is said to be strongly  $\lambda_p$ -summable ( $0 < p < \infty$ ) to the limit  $L$  [14] if

$$\lim_n \frac{1}{\lambda_n} \sum_{k \in I_n} |x_k - L|^p = 0, \quad (6)$$

and we write it as  $x_k \rightarrow L[V_\lambda]_p$ . In this case  $L$  is called the  $[V_\lambda]_p$ -limit of  $x$ .

The following relation was established in [14].

**Theorem 1.** *If  $0 < p < \infty$  and a sequence  $x = (x_k)$  is strongly  $\lambda_p$ -summable to  $L$ , then it is  $\lambda$ -statistically convergent to  $L$ . If a bounded sequence is  $\lambda$ -statistically convergent to  $L$ , then it is strongly  $\lambda_p$ -summable to  $L$ .*

The following theorem is  $\lambda$ -statistical version of Connor's Decomposition Theorem [16].

**Theorem 2.** *If  $x = (x_k)$  is strongly  $\lambda_p$ -summable or statistically  $\lambda$ -convergent to  $L$ , then there is a convergent sequence  $y$  and a  $\lambda$ -statistically null sequence  $z$  such that  $y$  is convergent to  $L$ ,  $x = y + z$  and*

$$\lim_n \frac{1}{\lambda_n} |\{k \in I_n : z_k \neq 0\}| = 0. \quad (7)$$

Moreover, if  $x$  is bounded, then  $y$  and  $z$  both are bounded.

*Proof.* By Theorem 1, it follows that  $x$  is  $\lambda$ -statistically convergent to  $L$  if  $x$  is strongly  $\lambda_p$ -summable to  $L$ . Set  $N_0 = 0$  and choose a strictly increasing sequence of positive integers  $N_1 < N_2 < N_3 < \dots$  such that

$$\frac{1}{\lambda_n} |\{k \in I_n : |x_k - L| \geq j^{-1}\}| < j^{-1} \quad (8)$$

for  $n > N_j$ . Define  $y$  and  $z$  as follows.

If  $N_0 < k < N_1$  set  $z_k = 0$  and  $y_k = x_k$ . Let  $j \geq 1$  and  $N_j < k \leq N_{j+1}$ . Now we set

$$y_k = \begin{cases} x_k, & z_k = 0, & \text{if } |x_k - L| < j^{-1}; \\ L, & z_k = x_k - L, & \text{if } |x_k - L| \geq j^{-1}. \end{cases} \quad (9)$$

Clearly,  $x = y + z$  and  $y$  and  $z$  are bounded, if  $x$  is bounded. Also, we observe that for  $k > N_j$ , we have

$$\begin{aligned} |y_k - L| < \epsilon & \quad \text{since } |y_k - L| = |x_k - L| < \epsilon \\ & \quad \text{if } |x_k - L| < j^{-1}, \\ |y_k - L| = |L - L| = 0 & \quad \text{if } |x_k - L| \geq j^{-1}. \end{aligned} \quad (10)$$

Hence,  $\lim_k y_k = L$ , since  $\epsilon$  was arbitrary.

Next we observe that

$$|\{k \in I_n : z_k \neq 0\}| \geq |\{k \in I_n : |z_k| \geq \epsilon\}| \quad (11)$$

for any natural number  $n$  and  $\epsilon > 0$ . Hence,  $\lim_n (1/\lambda_n) |\{k \in I_n : z_k \neq 0\}| = 0$ ; that is,  $z$  is  $\lambda$ -statistically null.

We now show that if  $\delta > 0$  and  $j \in \mathbb{N}$  such that  $j^{-1} < \delta$ , then  $|\{k \in I_n : z_k \neq 0\}| < \delta$  for all  $n > N_j$ . Recall from the construction that if  $N_j < k \leq N_{j+1}$ , then  $z_k \neq 0$  only if  $|x_k - L| > j^{-1}$ . It follows that if  $N_\ell < k \leq N_{\ell+1}$ , then

$$\{k \in I_n : z_k \neq 0\} \subseteq \{k \in I_n : |x_k - L| > \ell^{-1}\}. \quad (12)$$

Consequently,

$$\begin{aligned} \frac{1}{\lambda_n} |\{k \in I_n : z_k \neq 0\}| & \leq \frac{1}{\lambda_n} |\{k \in I_n : |x_k - L| > \ell^{-1}\}| \\ & < \ell^{-1} < j^{-1} < \delta, \end{aligned} \quad (13)$$

if  $N_\ell < n \leq N_{\ell+1}$  and  $\ell > j$ . That is,

$$\lim_n \frac{1}{\lambda_n} |\{k \in I_n : z_k \neq 0\}| = 0. \quad (14)$$

This completes the proof of the theorem.  $\square$

### 3. Application to Fourier Series

Let  $f : \mathbb{T} \rightarrow \mathbb{C}$  be a Lebesgue integrable function on the torus  $\mathbb{T} := [-\pi, \pi)$ ; that is,  $f \in L^1(\mathbb{T})$ . The Fourier series of  $f$  is defined by

$$f(x) \sim \sum_{j \in \mathbb{Z}} \widehat{f}(j) e^{ijx}, \quad x \in \mathbb{T}, \quad (15)$$

where the Fourier coefficients  $\widehat{f}(j)$  are defined by

$$\widehat{f}(j) := \frac{1}{2\pi} \int_{\mathbb{T}} f(t) e^{-ijt} dt, \quad j \in \mathbb{Z}. \quad (16)$$

The symmetric partial sums of the series in (15) are defined by

$$s_k(f; x) := \sum_{|j| \leq k} \widehat{f}(j) e^{ijx}, \quad x \in \mathbb{T}, k \in \mathbb{N}. \quad (17)$$

The conjugate series to the Fourier series in (15) is defined by [17, Vol. I, pp. 49]

$$\sum_{j \in \mathbb{Z}} (-i \operatorname{sgn} j) \widehat{f}(j) e^{ijx}. \quad (18)$$

Clearly, it follows from (15) and (18) that

$$\begin{aligned} & \sum_{j \in \mathbb{Z}} \widehat{f}(j) e^{ijx} + i \sum_{j \in \mathbb{Z}} (-i \operatorname{sgn} j) \widehat{f}(j) e^{ijx} \\ &= 1 + 2 \sum_{j=1}^{\infty} \widehat{f}(j) e^{ijx}, \end{aligned} \tag{19}$$

and the power series

$$1 + 2 \sum_{j=1}^{\infty} \widehat{f}(j) e^{ijx}, \quad \text{where } z := re^{ix}, \quad 0 \leq r < 1, \tag{20}$$

is analytic on the open unit disk  $|z| < 1$ , due to the fact that

$$|\widehat{f}(j)| \leq \frac{1}{2\pi} \int_{\pi} |f(t)| dt, \quad j \in \mathbb{Z}. \tag{21}$$

The conjugate function  $\widehat{f}$  of a function  $f \in L^1(\mathbb{T})$  is defined by

$$\begin{aligned} \widehat{f}(x) &:= -\lim_{\varepsilon \downarrow 0} \frac{1}{\pi} \int_{\varepsilon \leq |t| \leq \pi} \frac{f(x+t)}{2 \tan(t/2)} dt \\ &= \lim_{\varepsilon \downarrow 0} \frac{1}{\pi} \int_{\varepsilon}^{\pi} \frac{f(x-t) - f(x+t)}{2 \tan(t/2)} dt \end{aligned} \tag{22}$$

in the ‘‘principal value’’ sense and that  $\widehat{f}(x)$  exists at almost every  $x \in \mathbb{T}$ .

The following is  $\lambda$ -statistical version of [18] (c.f. [19, Theorem 2.1 (ii)]).

**Theorem 3.** *If  $f \in L^1(\mathbb{T})$ , then for any  $p > 0$  its Fourier series is strongly  $\lambda_p$ -summable to  $f(x)$  at almost every  $x \in \mathbb{T}$ . Furthermore, its conjugate series (18) is strongly  $\lambda_p$ -summable for any  $p > 0$  to the conjugate function  $\widehat{f}(x)$  defined in (22) at almost every  $x \in \mathbb{T}$ .*

From Theorems 1 and 3, we easily get the following useful result.

**Theorem 4.** *If  $f \in L^1(\mathbb{T})$ , then its Fourier series is  $\lambda$ -statistically convergent to  $f(x)$  at almost every  $x \in \mathbb{T}$ . Furthermore, its conjugate series (18) is  $\lambda$ -statistically convergent to the conjugate function  $\widehat{f}(x)$  defined in (22) at almost every  $x \in \mathbb{T}$ .*

### 4. $\lambda$ -Statistical Convergence in Paranormed Space

Recently, statistical convergence, statistical Cauchy, and strongly Cesàro summability have been studied in Paranormed Space by Alotaibi and Alroqi [11].

In this paper, we define and study the notion of  $\lambda$ -summable,  $\lambda$ -statistical convergence,  $\lambda$ -statistical Cauchy, and strongly  $\lambda_p$ -summability in Paranormed Space.

Let  $(X, g)$  be a Paranormed Space.

A sequence  $x = (x_k)$  is said to be *convergent* to the number  $\xi$  in  $(X, g)$  if, for every  $\varepsilon > 0$ , there exists a positive integer  $k_0$  such that  $g(x_k - \xi) < \varepsilon$  whenever  $k \geq k_0$ . In this case, we write  $g\text{-lim } x = \xi$ , and  $\xi$  is called the *g-limit* of  $x$ .

We define the following.

*Definition 5.* A sequence  $x = (x_k)$  is said to be  $\lambda$ -statistically convergent to the number  $\xi$  in  $(X, g)$  if, for each  $\varepsilon > 0$ ,

$$\lim_n \frac{1}{\lambda_n} |\{k \in I_n : g(x_k - \xi) \geq \varepsilon\}| = 0. \tag{23}$$

In this case we write  $\operatorname{st}_{\lambda}(g)\text{-lim } x = \xi$ .

*Definition 6.* A sequence  $x = (x_k)$  is said to be  $\lambda$ -statistically Cauchy sequence in  $(X, g)$  if for every  $\varepsilon > 0$  there exists a number  $N = N(\varepsilon)$  such that

$$\lim_n \frac{1}{\lambda_n} |\{j \in I_n : g(x_j - x_N) \geq \varepsilon\}| = 0. \tag{24}$$

*Definition 7.* A sequence  $x = (x_k)$  is said to be *strongly  $\lambda_p$ -summable* ( $0 < p < \infty$ ) to the *limit*  $\xi$  in  $(X, g)$  if

$$\lim_n \frac{1}{\lambda_n} \sum_{k \in I_n} (g(x_k - \xi))^p = 0, \tag{25}$$

and we write it as  $x_k \rightarrow \xi[V_{\lambda}, g]_p$ . In this case  $\xi$  is called the  $[V_{\lambda}, g]_p$ -limit of  $x$ .

Now we define another type of convergence in Paranormed Space.

*Definition 8.* A sequence  $(x_k)$  in a Paranormed Space  $(X, g)$  is said to  $\operatorname{st}_{\lambda}^*(g)$ -convergent to  $\xi \in X$  if there exists an index set  $K = \{k_1 < k_2 < \dots < k_n < \dots\} \subseteq \mathbb{N}$ ,  $n = 1, 2, \dots$ , with  $\delta_{\lambda}(K) = 1$  such that  $g(x_{k_n} - \xi) \rightarrow 0$  ( $n \rightarrow \infty$ ). In this case, we write  $\xi = \operatorname{st}_{\lambda}^*(g)\text{-lim } x$ .

First we prove the following results on  $\lambda$ -statistical convergence in  $(X, g)$ .

**Theorem 9.** *If  $g\text{-lim } x = \xi$ , then  $\operatorname{st}_{\lambda}(g)\text{-lim } x = \xi$  but converse need not be true in general.*

*Proof.* Let  $g\text{-lim } x = \xi$ . Then, for every  $\varepsilon > 0$ , there is a positive integer  $N$  such that

$$g(x_n - \xi) < \varepsilon \tag{26}$$

for all  $n \geq N$ . Since the set  $A(\varepsilon) := \{k \in \mathbb{N} : g(x_k - \xi) \geq \varepsilon\}$  is finite,  $\delta_{\lambda}(A(\varepsilon)) = 0$ . Hence,  $\operatorname{st}_{\lambda}(g)\text{-lim } x = \xi$ .

The following example shows that the converse need not be true.

*Example 10.* Let  $X = \ell(1/k) := \{x = (x_k) : \sum_k |x_k|^{1/(k+1)} < \infty\}$  with the paranorm  $g(x) = (\sum_k |x_k|^{1/(k+1)})$ . Define a sequence  $x = (x_k)$  by

$$x_k := \begin{cases} k, & \text{if } n - [\lambda_n] + 1 \leq k \leq n, n \in \mathbb{N}; \\ 0, & \text{otherwise,} \end{cases} \tag{27}$$

and write

$$K(\varepsilon) := \{k \leq n : g(x_k) \geq \varepsilon\}, \quad 0 < \varepsilon < 1. \tag{28}$$

We see that

$$g(x_k) := \begin{cases} k^{1/(k+1)}, & \text{if } n - [\lambda_n] + 1 \leq k \leq n, n \in \mathbb{N}; \\ 0, & \text{otherwise,} \end{cases} \quad (29)$$

and hence

$$\lim_k g(x_k) := \begin{cases} 1, & \text{if } n - [\lambda_n] + 1 \leq k \leq n, n \in \mathbb{N}; \\ 0, & \text{otherwise.} \end{cases} \quad (30)$$

Therefore  $g$ -lim  $x$  does not exist. On the other hand  $\delta_\lambda(K(\varepsilon)) = 0$ ; that is,  $st_\lambda(g)$ -lim  $x = 0$ .

This completes the proof of the theorem.  $\square$

We can easily prove the following results on  $\lambda$ -statistical convergence in  $(X, g)$  similar to those of [11].

**Theorem 11.** *If a sequence  $x = (x_k)$  is  $\lambda$ -statistically convergent in  $(X, g)$ , then  $st_\lambda(g)$ -limit is unique.*

**Theorem 12.** *Let  $st_\lambda(g)$ -lim  $x = \xi_1$  and  $st_\lambda(g)$ -lim  $y = \xi_2$ . Then,*

- (i)  $st_\lambda(g)$ -lim  $(x \pm y) = \xi_1 \pm \xi_2$ ,
- (ii)  $st_\lambda(g)$ -lim  $\alpha x = \alpha \xi_1$ ,  $\alpha \in \mathbb{R}$ .

**Theorem 13.** *Let  $(X, g)$  be a complete Paranormed Space. Then a sequence  $x = (x_k)$  of points in  $(X, g)$  is  $\lambda$ -statistically convergent if and only if it is  $\lambda$ -statistically Cauchy.*

**Theorem 14.** (a) *If  $0 < p < \infty$  and  $x_k \rightarrow \xi[V_\lambda, g]_p$ , then  $x = (x_k)$  is  $\lambda$ -statistically convergent to  $\xi$  in  $(X, g)$ .*

(b) *If  $x = (x_k)$  is bounded and  $\lambda$ -statistically convergent to  $\xi$  in  $(X, g)$ , then  $x_k \rightarrow \xi[V_\lambda, g]_p$ .*

**Theorem 15.** *Let  $(X, g)$  be a complete Paranormed Space. Then a sequence  $x = (x_k)$  of points in  $(X, g)$  is  $\lambda$ -statistically convergent if and only if it is  $\lambda$ -statistically Cauchy.*

Note that the proof of Theorem 2.4 [11] is incorrect and the correct proof is given in the following theorem which is generalization of Theorem 2.4 [11]. Another form of this result is given in [20] for ideal convergence.

**Theorem 16.** *A sequence  $x = (x_k)$  in  $(X, g)$  is  $\lambda$ -statistically convergent to  $\xi$  if and only if it is  $st_\lambda^*(g)$ -convergent to  $\xi$ .*

*Proof.* Suppose that  $x = (x_k)$  is  $\lambda$ -statistically convergent to  $\xi$ ; that is,  $st_\lambda(g)$ -lim  $x = \xi$ . Now, write for  $r = 1, 2, \dots$

$$K_r := \left\{ n \in \mathbb{N} : g(x_{k_n} - \xi) \geq \frac{1}{r} \right\}, \quad (31)$$

$$M_r := \left\{ n \in \mathbb{N} : g(x_{k_n} - \xi) < \frac{1}{r} \right\} \quad (r = 1, 2, \dots).$$

Then  $\delta_\lambda(K_r) = 0$ ,

$$M_1 \supset M_2 \supset \dots \supset M_i \supset M_{i+1} \supset \dots, \quad (32)$$

$$\delta_\lambda(M_r) = 1, \quad r = 1, 2, \dots \quad (33)$$

Now we have to show that, for  $n \in M_r$ ,  $(x_{k_n})$  is  $g$ -convergent to  $\xi$ . On contrary suppose that  $(x_{k_n})$  is not  $g$ -convergent to  $\xi$ . Therefore, there is  $\varepsilon > 0$  such that  $g(x_{k_n} - \xi) \geq \varepsilon$  for infinitely many terms. Let  $M_\varepsilon := \{n \in \mathbb{N} : g(x_{k_n} - \xi) < \varepsilon\}$  and  $\varepsilon > 1/r, r \in \mathbb{N}$ .

Then

$$\delta_\lambda(M_\varepsilon) = 0, \quad (34)$$

and by (32),  $M_r \subset M_\varepsilon$ . Hence  $\delta_\lambda(M_r) = 0$ , which contradicts (33) and we get that  $(x_{k_n})$  is  $g$ -convergent to  $\xi$ . Hence,  $x$  is  $st_\lambda^*(g)$ -convergent to  $\xi$ .

Conversely, suppose that  $x$  is  $st_\lambda^*(g)$ -convergent to  $\xi$ . Then there exists a set  $K = \{k_1 < k_2 < k_3 < \dots < k_n < \dots\}$  with  $\delta_\lambda(K) = 1$  such that  $g$ -lim $_{n \rightarrow \infty} x_{k_n} = \xi$ . Therefore, there is a positive integer  $N$  such that  $g(x_{k_n} - \xi) < \varepsilon$  for  $n \geq N$ . Put  $K_\varepsilon := \{n \in \mathbb{N} : g(x_n - \xi) \geq \varepsilon\}$  and  $K' := \{k_{N+1}, k_{N+2}, \dots\}$ . Then  $\delta_\lambda(K') = 1$  and  $K_\varepsilon \subseteq \mathbb{N} - K'$  which implies that  $\delta_\lambda(K_\varepsilon) = 0$ . Hence  $x = (x_k)$  is  $\lambda$ -statistically convergent to  $\xi$ ; that is  $st_\lambda(g)$ -lim  $x = \xi$ .

This completes the proof of the theorem.  $\square$

### Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

### Acknowledgment

This work was funded by the Deanship of Scientific Research (DSR), King Abdulaziz University, Jeddah, under Grant no. (130-073-D1434). The authors, therefore, acknowledge with thanks DSR technical and financial support.
