## A NOTE ON LIMITING BEHAVIOUR OF DISASTROUS ENVIRONMENT EXPONENTS

Thomas S. Mountford<br>Department of Mathematics<br>University of California, Los Angeles<br>Los Angeles, CA 90095-1555<br>malloy@math.ucla.edu

#### Abstract

We consider a random walk on the d-dimensional lattice and investigate the asymptotic probability of the walk avoiding a "disaster" (points put down according to a regular Poisson process on space-time). We show that, given the Poisson process points, almost surely, the chance of surviving to time t is like $e^{-\alpha \log \left(\frac{1}{k}\right) t}$, as t tends to infinity if $k$, the jump rate of the random walk, is small.

Keywords Random walk, disaster point, Poisson process

## Introduction

This note concerns a recent work of T. Shiga ([Shi]). The following model was considered: We are given a system of independent rate one Poisson processes on $[0, \infty), \underline{N}=\left\{N_{x}(t)\right\}_{x \in \mathbb{Z}^{d}}$. We are also given an independent simple random walk on $\mathbb{Z}^{d}, X(t)$, moving at rate $k$ and with, say, $X(0)=\underline{0}$.
Of course simply by integrating out over $\underline{N}, X$ we have (taking $\delta N_{X(s)}(s)=N_{X(s)}(s)-$ $\left.N_{X(s)}(s-)\right)$

$$
\forall t \geq 0 \quad P\left[\forall 0 \leq s \leq t \delta N_{X(s)}(s)=0\right]=e^{-t}
$$

The problem becomes non-trivial when considering

$$
\begin{gathered}
p(t, N)=P\left[\forall 0 \leq s \leq t \delta N_{X(s)}(s)=0 \mid \underline{N}\right]= \\
P\left[\forall 0 \leq s \leq t \delta N_{X(s)}(s)=0 \mid \underline{N}(s) s \leq t\right] .
\end{gathered}
$$

It is non-trivial, but was shown in [Shi], that the random quantity $p(t, N)$ satisfies

$$
\lim _{t \rightarrow \infty} \frac{\log p(t, N)}{t}=-\lambda(d, k)
$$

It was shown that as $k$ becomes large $\lambda$ tends to one in all dimensions and that in dimensions three and higher $\lambda$ is equal to one for $k$ sufficiently large. The focus of this note is on the other behaviour of $\lambda(d, k)$ : the behaviour as $k \rightarrow 0$. It was shown in [Shi] that there existed two constants $c_{1}, c_{2} \in(0, \infty)$ so that

$$
c_{1}<\liminf _{k \rightarrow 0} \frac{\lambda(d, k)}{\log \left(\frac{1}{k}\right)} \leq \limsup _{k \rightarrow 0} \frac{\lambda(d, k)}{\log \left(\frac{1}{k}\right)}<c_{2}
$$

We wish to show
Theorem 1.0 There exists a constant $\alpha$ so that $\lim \frac{\lambda(d, k)}{\log \left(\frac{1}{k}\right)}=\alpha$.
The paper is organized as follows: in Section One we consider a "shortest path" problem which is easily and naturally dealt with by Liggett's subadditive ergodic theorem (see [L]). This yield a constant $\alpha$. In Section Two we show (Corollary 2.4) that $\lim \inf _{k \rightarrow 0} \frac{\lambda(d, k)}{\log \left(\frac{1}{k}\right)} \geq \alpha$ and in Section Three we show (Corollary 3.1) $\lim \sup _{k \rightarrow 0} \frac{\lambda(d, k)}{\log \left(\frac{1}{k}\right)} \leq \alpha$, thus completing the proof of Theorem 1.0 .

Both of the last two sections rely heavily on block arguments as popularized in [D], [D1].
Acknowledgement This paper was conceived during a visit to the Tokyo Institute of Technology in January of this year. It is a pleasure to thank Professor Shiga for his clear exposition of the area and for his generosity as host.
I wish also to thank the referee for a thorough reading which has resulted in a much clearer paper.

## Section One

In this section we consider only the Poisson processes $N$. The random walk will not be directly considered at all, though sometimes it will be implicit, as in the definition of a path below:
A path $\gamma$ is a piecewise constant right continuous function with left limits
$[0, \infty) \rightarrow \mathbb{Z}^{d}$ so that for all $\mathrm{t}\|\gamma(t)-\gamma(t-)\|_{1} \leq 1$.
The collection of paths beginning at $x \in \mathbb{Z}^{d}$ which avoid points in $N$ up to time $t$ will be denoted by $\Gamma^{x, t}$. More formally

$$
\Gamma^{x, t}=\left\{\gamma: \forall 0 \leq s \leq t \delta N_{\gamma(s)}(s)=0, \gamma(0)=x\right\} .
$$

(Again, consistent with previous notation, $\delta N_{\gamma(s)}=N_{\gamma(s)}(s)-N_{\gamma(s)}(s-)$.) For $\gamma \in$ $\Gamma^{x, t}, S^{x}(\gamma, t)=\sum_{0 \leq s \leq t} I_{\gamma(s) \neq \gamma(s-)}$ where $I$ is the usual indicator function. In words S counts the number of jumps that $\gamma$ makes in time interval $[0, t]$. If $x=0$ we suppress the suffix $x$.
Finally we define

$$
\alpha(t, N)=\min \left\{S(\gamma, t): \gamma \in \Gamma^{t}=\Gamma^{0, t}\right\} .
$$

Proposition $1.1 \alpha=\lim _{t \rightarrow \infty} \frac{1}{t} \alpha(t, N)$ exists.
Proof Define random variables $X_{s, t}$ for $0 \leq s<t<\infty$ by

$$
X_{0, t}=\alpha(t, N)
$$

and for $0<s<t$

$$
X_{s, t}=\inf \left\{S(\gamma, t)-S(\gamma, s): \gamma \in \Gamma^{t}, \gamma(s)=x_{s}\right\}
$$

where $x_{s}=\min \left\{x \in \mathbb{Z}^{d}: \exists \gamma \in \Gamma^{s}\right.$ so that $\left.S(\gamma, s)=\alpha(s, N), \gamma(s)=x\right\}$ under any well ordering of the points $x \in \mathbb{Z}^{d}$.
Then the random variables satisfy the conditions for Liggett's subadditive ergodic theorem. Given the ergodicity of our Poisson processes we conclude that the a.s. limit of $\frac{1}{t} \alpha(t, N)$ is non random.

We now show that the constant $\alpha$ of Proposition 1.1 is strcitly positive. This fact will follow from Theorem 1.0 and the results of [Shi], however we include it for completeness and because the argument given is a precursor to the block argument of Proposition 2.2.

Proposition 1.2 The constant $\alpha$ is strictly positive.

Fix $\varepsilon>0$ small we shall give conditions on the smallness of $\varepsilon$ as the proof progresses. Choose integer $L$ so that $L^{d} e^{-L}<\varepsilon$.
We divide up space time into cubes

$$
V(\underline{n}, r)=\left[n_{1} L,\left(n_{1}+1\right) L\right) \times\left[n_{2} L,\left(n_{2}+1\right) L\right) \times \cdots\left[n_{d} L,\left(n_{d}+1\right) L\right) \times[r L,(r+1) L) .
$$

We associate 0-1 random variables $\psi(\underline{n}, r)$ to these cubes by taking $\psi(\underline{n}, r)$ to be 1 if and only if

$$
\forall x \in\left[n_{1} L,\left(n_{1}+1\right) L\right) \times\left[n_{2} L,\left(n_{2}+1\right) L\right) \times \cdots\left[n_{d} L,\left(n_{d}+1\right) L\right)
$$

$$
N_{x}((r+1) L-)-N_{x}(r L) \geq 1 .
$$

We note that the $\psi$ random variables are i.i.d. and that, by the choice of $L$, the probability that $\psi(\underline{n}, r) \neq 1$ is $<\varepsilon$.
To show our result it is sufficient to show that as $m$ tends to infinity $\alpha(m L, N) \geq \frac{m}{2}$ with probability tending to one.
The trace of a path $\gamma \in \Gamma^{m L}$ is the sequence of points in $\mathbb{Z}^{d}, \underline{n}_{i} 0 \leq i \leq m$ so that for $0 \leq i \leq m$,

$$
(\gamma(i L), i L) \in V\left(\underline{n}_{i}, i L\right) .
$$

The crucial observation is that for such $\gamma, \underline{n}_{i}$,

$$
S^{0}(\gamma, m L) \geq \sum_{i=0}^{m-1} \psi\left(\underline{n}_{i}, i\right) \mid+L \sum_{i=0}^{m-1}\left(\left\|\underline{n}_{i+1}-\underline{n}_{i}\right\|_{\infty}-1\right)_{+}
$$

since if $\psi\left(\underline{n}_{i}, i\right)=1$ then $\gamma$ must make at least one jump in the time interval $[i R,(i+1) R)$ and if, furthermore $\left(\left\|\underline{n}_{i+1}-\underline{n}_{i}\right\|_{\infty}-1\right)_{+}=f$, then in this time interval $\gamma$ must make more than $f L$ jumps.
Thus to show that $\alpha(m L, N) \geq \frac{m}{2}$ it suffices to show that for all $\left\{\underline{n}_{i}\right\}$ with

$$
\begin{equation*}
\sum_{i=0}^{m-1}\left(\left\|\underline{n}_{i+1}-\underline{n}_{i}\right\|_{\infty}-1\right)_{+} \leq \frac{m}{2 L} \tag{1}
\end{equation*}
$$

it is the case that

$$
\left\{\sum_{i=0}^{m-1} \psi\left(\underline{n}_{i}, i\right) \left\lvert\, \geq \frac{m}{2}\right.\right\} .
$$

By simple large deviations arguments the probability that for any given $\left\{\underline{n}_{i}\right\},\left\{\sum_{i=0}^{m-1} \psi\left(\underline{n}_{i}, i\right) \mid \geq\right.$ $\left.\frac{m}{2}\right\}$ is less than $2^{m}(\varepsilon)^{\frac{m}{2}}$. Thus it remains only to count the number of $\{\underline{n}\}$ satisfying (1).
We write (for positive integer $\left.g_{i}\right) A\left(g_{1}, g_{2}, \cdots, g_{m}\right)$ for the set of $\left(\underline{n}_{1}, \underline{n}_{2}, \cdots \underline{n}_{m}\right)$ so that for $1 \leq i \leq m,\left(\left\|\underline{n}_{i}-\underline{n}_{i-1}\right\|_{\infty}-1\right)_{+}=g_{i}$. We first give a crude bound on the cardinality of $A\left(g_{1}, g_{2}, \cdots g_{n}\right): \underline{n}_{0}$ is required to be $\underline{0}$, after having "chosen" $\underline{n}_{0}, \underline{n}_{1} \cdots \underline{n}_{i-1}$ we have $3^{d}$ choices for $\underline{n}_{i}$ if $g_{i}=0$, otherwise we have at most $2 d\left(2 g_{i}+3\right)^{d-1}$ choices for $\underline{n}_{i}$. Thus (using $2 d \leq 3^{d}$ )

$$
\left|A\left(g_{1}, g_{2}, \cdots g_{m}\right)\right| \leq 3^{m d} \prod\left(2 g_{i}+3\right)^{d-1}
$$

We may find $K$ so that for all $g,(2 g+3)^{d-1} \leq K 2^{g}$; we conclude that

$$
\left|A\left(g_{1}, g_{2}, \cdots g_{m}\right)\right| \leq 3^{m d} K^{m} 2^{\sum_{i=1}^{m} g_{i}} \leq C^{m}
$$

for some universal $C$ not depending on $d, \varepsilon$, if $\sum g_{i} \leq \frac{m}{2 L}$.
By elementary combinatorics the number of $\left(g_{1}, g_{2}, \cdots g_{m}\right)$ so that $\sum_{i=1}^{m} g_{i}=r$ is $\binom{m+r-1}{r}$, thus the number of $\left(g_{1}, g_{2}, \cdots, g_{m}\right)$ so that $\sum_{i=1}^{m} g_{i} \leq \frac{m}{2 L}$ is less than $2^{2 m}$. We conclude that the number of $\left\{\underline{n}_{i}\right\}$ satisfying (1) is bounded by $(4 C)^{m}$. Thus the probability that $\alpha(m L, N)$ exceeds $\frac{m}{2}$ is at least $1-(4 C)^{m} 2^{m}(\varepsilon)^{\frac{m}{2}}$. This tends to one as $m$ tends to infinity provided that $\varepsilon$ was fixed sufficiently small.

## Section Two

Fix $\varepsilon>0$, arbitrarily small. Given $c>0$ fixed, we say that a cube $[-c R, c R]^{d}$ is good if $\forall x \in[-c R, c R]^{d}$

$$
\inf _{\gamma \in \Gamma^{x, R}} S^{x}(\gamma, R) \geq R(\alpha-\varepsilon)
$$

Lemma 2.1 Given $\delta, c>0$, there exists $R_{0}=R_{0}(c, \delta)$ so that for all $R \geq R_{0}$,

$$
P\left[[-c R, c R]^{d} \text { is good }\right] \geq 1-\delta
$$

Proof Given $\varepsilon, c$, there exists $k$ so that for any $R$, we can pick points
$x_{1}^{R}, x_{2}^{R} \cdots x_{k / \varepsilon^{d}}^{R} \in[-c R, c R]^{d}$ so that every point of $[-c R, c R]^{d}$ is within $R \varepsilon / 10$ of $x_{j}^{R}$ for at least one $j$. Given this property it is clear that event

$$
\left\{\inf _{x \in[-c R, c R]^{d}} \inf _{\gamma \in \Gamma^{x, R}} S(\gamma, R)<R(\alpha-\varepsilon)\right\}
$$

is contained in

$$
\left\{\inf _{x_{j}^{R}} \inf _{\gamma \in \Gamma^{x_{j}^{R}, R}} S(\gamma, R)<R(\alpha-\varepsilon / 2)\right\}
$$

Thus we have

$$
P\left[[-c R, c R]^{d} \text { is good }\right] \geq 1-\frac{k}{\varepsilon^{d}} P[\alpha(R, N)<R(\alpha-\varepsilon / 2)]
$$

This last term is greater than $1-\delta$ if $R$ is sufficiently large.

We have not fully specified how small we require $\delta$ to be but, conditional on this we will fix $R$ at a level so large that the conclusions of Lemma 2.1 hold for $\delta$ and also so that $\gg \frac{1}{\varepsilon}$.

Lemma 2.2 Given $c$ and $R \geq R_{0}$ fixed, there exists $k_{0}>0$ so that if $0<k \leq k_{0}$ and cube $[-c R, c R]^{d}$ is good then for any random walk $X(t)$ starting in the cube, the chance of survival to time $R$ is bounded above by $k^{R(\alpha-2 \varepsilon)}$. More generally given $c, R \geq R_{0}$ we have for $k \leq k_{0}$ that the chance that the random walk makes $\geq f \alpha R$ jumps in time $R$ is bounded above by $k^{f R(\alpha-\varepsilon)}$.

Proof Let the starting point of $X$ be x. By definition of $\alpha(R, N)$ and a cube being good we have

$$
P\left[X(\cdot) \in \Gamma^{x, R}\right] \leq P[S(X(.), R) \geq R(\alpha-\varepsilon)] \leq(R k)^{R(\alpha-\varepsilon)}
$$

This latter term is less than $k^{R(\alpha-2 \varepsilon)}$ if $k$ is sufficiently small.
We choose $c$ to equal $10(\alpha+1)$ and divide up the lattice into cubes $C(\underline{n})=2 c R \underline{n}+[-c R, c R]^{d}$. We divide up space time into cubes $D(\underline{n}, i)=C(\underline{n}) \times[i R,(i+1) R]$. We say that $D(\underline{n}, i)$ is good if $[-c R, c R]^{d}$ is good (in the old sense) after translating Poisson system $(\underline{N})$ spatially by $2 c R \underline{n}$ and temporally by $i R$.

We define random variables $\psi(\underline{n}, i)$ taking values 0 or 1 by

$$
\psi(\underline{n}, i)=1 \text { if } D(\underline{n}, i) \text { is good. }
$$

The random variables $\psi(\underline{n}, i)$ are not independent, but it should be noted that random variables $\psi\left(\underline{n}_{1}, i_{1}\right), \psi\left(\underline{n}_{2}, i_{2}\right) \cdots \psi\left(\underline{n}_{j}, i_{j}\right)$ are independent if the $i_{h} \mathrm{~s}$ are all distinct.
A $v$-chain $\beta$ is a sequence $\left(\beta_{j}, j\right) j=0,1, \cdots v-1$. We do not require that $\left|\beta_{j+1}-\beta_{j}\right|_{1}$ be less than or equal to 1 .
An $(r-v)$-chain is a sequence $\left(\beta_{j}, j\right) j=r, r+1, \cdots v-1$.
Given $\psi$ we associate a score to a $(r-v)$-chain $\beta$ by

$$
J_{v}(\beta)=\sum_{j=r}^{j=v-1} \psi\left(\beta_{j}, j\right)+9 \sum_{j=r}^{j=v-2}\left(\left|\beta_{j+1}-\beta_{j}\right|_{\infty}-1\right)_{+}
$$

Proposition 2.1 For a random walk starting at time $r R$ in cube $C(\underline{n})$, the chance that it survives until time $v R$ is bounded above by

$$
2^{v-r-1} \exp \left(R(\alpha-2 \varepsilon) \ln (k) \min _{\beta} J_{v}(\beta)\right)
$$

where the minimum is taken over all ( $r-v$ )-chains $\beta$ with $\beta_{r}=\underline{n}$.

Proof In the proof we regard $v$ as fixed and use induction on $k=v-r$. The proof follows from induction on $k$. It is clearly true for $k=1$ (or $r=v-1$ ) and all $\underline{n}$ by Lemma 2.2. Suppose that it is true for $k-1$ (and all possible $\underline{n}$ ) and suppose further that $X^{k}$ is a random walk starting at time $R(v-k)$ in cube $C(\underline{n})$. We consider the random walk over time interval $[(v-k) R,(v-k+1) R]$.

$$
\begin{gathered}
\quad P\left[X^{k} \text { survives up to } v R\right]= \\
\sum_{\underline{m}} P\left[X^{k} \text { survives up to }(v-k+1) R\right. \\
\left.X^{k}(v-k+1) R \in C(\underline{m}), X^{k} \text { survives up to } v R\right] .
\end{gathered}
$$

By the Markov property for $X^{k}$ and induction this summation is bounded by

$$
\begin{gathered}
\sum_{\underline{m}} P\left[X^{k} \text { survives up to }(v-k+1) R,\right. \\
\left.X^{k}(v-k+1) R \in C(\underline{m})\right]\left(2^{k-2}\right) \exp \left(R(\alpha-2 \varepsilon) \ln (k) J \frac{\underline{m}, k-1, v}{v}\right)
\end{gathered}
$$

where $J_{v}^{\underline{m}, k-1, v}$ is the minimum of $J_{v}(\beta)$ over $(v-k+1)-v$-chains $\beta$ with $\beta_{v-k+1}=\underline{m}$. This in turn is majorized by

$$
\sum_{f=2} P\left[X^{k} \text { survives up to }(v-k+1) R, X^{k}((v-k+1) R) \in C(\underline{m})\right.
$$

$$
\left.\begin{array}{c}
\text { with } \left.\|\underline{n}-\underline{m}\|_{\infty}=f\right]\left(2^{k-2}\right) \exp \left(R(\alpha-2 \varepsilon) \ln (k) J_{v}^{f, k-1, v}\right) \\
+\sum_{\left\|\underline{n}-\underline{n}^{\prime}\right\|_{\infty} \leq 1} P\left[X^{r} \text { survives up to }(v-k+1) R, X^{k}((v-k+1) R) \in C\left(\underline{n}^{\prime}\right)\right] \\
\left(2^{k-2}\right) \exp \left(R(\alpha-2 \varepsilon) \ln (k) J \underline{n}^{\prime}, k-1, v\right.
\end{array}\right)
$$

for $J_{v}^{f, k-1, v}$ the minimum of $J_{\underline{v}}^{\underline{m}, k-1, v}$ over $\|\underline{n}-\underline{m}\|_{\infty}=f$. By Lemma 2.2 these two summations are bounded by

$$
\begin{gathered}
\left(2^{k-2}\right) \exp \left((\alpha-2 \varepsilon) R \ln (k)\left(\psi(\underline{n}, r)+J_{v}^{1, k-1, v}\right)\right)+ \\
\left(2^{k-2}\right) \sum_{f=2}^{\infty} \exp \left((f-1) 10 \alpha R \ln (k)+R(\alpha-2 \varepsilon) \ln (k) J_{v}^{f, k-1, v}\right)
\end{gathered}
$$

where $J_{v}^{1, k-1, v}$ is the minimum of $J_{v}^{\underline{m}, k-1, v}$ over $\|\underline{n}-\underline{m}\|_{\infty} \leq 1$ (a slightly different definition from that of $J_{v}^{f, k-1, v}$ for higher $f$ ).
If $R$ was chosen sufficiently large this is bounded by

$$
2^{k-1} \exp \left(R(\alpha-2 \varepsilon) \ln (k) \min _{\beta} J_{v}(\beta)\right)
$$

where the minimum is taken over all (r-v)-chains $\beta$ with $\beta_{r}=\underline{n}$.
It remains to show that as $v$ tends to infinity $J_{v}(\beta)$ is roughly $v$. It is time to properly define $\delta$ First fix $K \gg 3^{d}$ and so that for each integer $f$ at least 1 , the number of $\underline{m}$ with $\|\underline{m}\|_{\infty}=f$ is less than $K 2^{f-1} / 100$.

Lemma 2.3 Given $\varepsilon>0$ there exists $\delta$ so that $0<\delta<\varepsilon / 100 K$ so that if $X_{1}, X_{2}, \cdots X_{N}$ are i.i.d. Bernoulli $\delta$ ) random variables for any integer $N$ then

$$
P\left[\sum_{j=1}^{N} X_{j} \geq N \varepsilon+r\right) \leq\left(\frac{1}{100 K}\right)^{N+r}
$$

Proposition 2.2 With probability one for all v sufficiently large

$$
\inf _{\beta \in J_{v}} J(\beta) \geq v(1-2 \varepsilon)
$$

Proof We simply count. Given our definition of $J(\beta)$ we need only consider those $\beta \in J_{v}$ with $\sum_{j=0}^{v-2}\left(\left\|\beta_{j+1}-\beta_{j}\right\|_{\infty}-1\right)_{+} \leq v / 9$. For $\beta \in J_{v}$ we say the code of $\beta$ is the sequence

$$
\left\{\left(\left\|\beta_{1}-\beta_{0}\right\|_{\infty}-1\right)_{+} \cdots\left(\left\|\beta_{j+1}-\beta_{j}\right\|_{\infty}-1\right)_{+} \cdots\left(\left\|\beta_{v-1}-\beta_{v-2}\right\|_{\infty}-1\right)_{+}\right\} .
$$

For fixed code $m_{0}, m_{1} \cdots m_{v-2}$ with $\sum m_{j} \leq v / 9$ there are (by our choice of K ) less than or equal to $K^{v-1} \prod_{j=0}^{j=v-2} 2^{m_{i}-1}$ possible v-chains. For any such $\beta, J_{v}(\beta)=9 \sum m_{j}+\sum \psi\left(\beta_{j}, j\right)$ and so

$$
P\left[J_{v}(\beta) \leq v(1-2 \varepsilon)\right] \leq P\left[\sum \psi\left(\beta_{j}, j\right) \leq v(1-2 \varepsilon)-9 \sum m_{j}\right]
$$

$$
=P\left[\sum\left(1-\psi\left(\beta_{j}, j\right)\right) \geq v 2 \varepsilon+9 \sum m_{j}\right] \leq\left(\frac{1}{100 K}\right)^{v}\left(\frac{1}{100 K}\right)^{9 \sum m_{j}} .
$$

So the probability that for some $\beta$ with code $m_{0}, m_{1}, \cdots m_{v-2} J_{v}(\beta)$ is less than or equal to $(1-2 \varepsilon) v$ is bounded by

$$
K^{v} \prod_{j=0}^{j=v-2} 2^{m_{i}-1}\left(\frac{1}{100 K}\right)^{v}\left(\frac{1}{100 K}\right)^{\sum m_{j}} \leq\left(\frac{1}{100}\right)^{v}
$$

But the number of codes which sum to less than $v / 9$ is (assuming w.l.o.g that $v / 9$ is an integer) exactly $\sum_{j=0}^{j=v / 9}\binom{v+j-1}{v-1} \leq v / 9\binom{v+v / 9-1}{v-1} \leq 2^{v}$ for v large. We conclude that $P\left[\min J_{v}(\beta) \leq\right.$ $v(1-2 \varepsilon)] \leq\left(\frac{1}{50}\right)^{v}$ for large v . The proposition now follows from the Borel Cantelli Lemma.

Corollary $2.4 \liminf _{k \rightarrow 0} \frac{\lambda(d, k)}{\ln \left(\frac{1}{k}\right)} \geq \alpha(d)$.
Proof By Proposition 2.1 we have that for $k \leq k_{0}$ that

$$
p(v R, N) \leq 2^{v-1} \exp \left(R(\alpha-2 \varepsilon) \ln (k) \min J_{v}(\beta)\right)
$$

By Proposition 2.2 we have therefore that for large enough $v$

$$
\begin{aligned}
& p(v R, N) \leq 2^{v-1} \exp (R(\alpha-2 \varepsilon) \ln (k) v(1-2 \varepsilon)) \\
& \quad \leq 2^{v R \varepsilon} \exp (R(\alpha-2 \varepsilon) \ln (k) v(1-2 \varepsilon)) \\
& \quad \leq \exp (R v((\alpha-2 \varepsilon) \ln (k)(1-2 \varepsilon)+\varepsilon))
\end{aligned}
$$

Thus we have that $\lambda(k, d) \geq \ln \left(\frac{1}{k}\right)(\alpha-2 \varepsilon)(1-2 \varepsilon)-\varepsilon$. Since $\varepsilon$ is arbitrarily small the Corollary follows.

## Section Three

In this section we will use block/percolation arguments that since [BG] may be regarded as standard. Simply to avoid notational encumbrance we will write out the proof for the case $d=1$ but the argument easily extends to all dimensions.
Fix $\varepsilon>0$. By Proposition 1.1 we have that for R sufficiently large

$$
P[\alpha(R, N) \leq R(\alpha+\varepsilon)]>1-\varepsilon^{6} .
$$

Now note that, by our definition of $\alpha$, the event $\{\alpha(R, N) \leq R(\alpha+\varepsilon)\}$ is the same as the event $\left\{\exists \gamma \in \Gamma^{R}\right.$ with $S(\gamma, R) \leq R(\alpha+\varepsilon)$ and $\left.|\gamma(R)| \leq R(\alpha+\varepsilon)\right\}$. Thus for $R$ sufficiently large

$$
\begin{aligned}
& \left\{\nexists \gamma \in \Gamma^{R} \text { with } S(\gamma, R) \leq R(\alpha+\varepsilon) \text { and } \gamma(R) \in[0, R(\alpha+\varepsilon)]\right\} \cap \\
& \left\{\nexists \gamma \in \Gamma^{R} \text { with } S(\gamma, R) \leq R(\alpha+\varepsilon) \text { and } \gamma(R) \in[-R(\alpha+\varepsilon), 0]\right\}
\end{aligned}
$$

has probability less than $\varepsilon^{6}$. These two events are increasing functions of the Poisson processes and, by symmetry, have equal probabilities, so by the FKG inequalities (as in [BG]) we have

$$
P\left[\nexists \gamma \in \Gamma^{R} \text { with } S(\gamma, R) \leq R(\alpha+\varepsilon) \text { and } \gamma(R) \in[0, R(\alpha+\varepsilon)]\right]<\varepsilon^{3}
$$

, that is,

$$
P\left[\exists \gamma \in \Gamma^{R} \text { with } S(\gamma, R) \leq R(\alpha+\varepsilon) \text { and } \gamma(R) \in[0, R(\alpha+\varepsilon)]\right]>1-\varepsilon^{3}
$$

and, by symmetry,

$$
P\left[\exists \gamma \in \Gamma^{R} \text { with } S(\gamma, R) \leq R(\alpha+\varepsilon) \text { and } \gamma(R) \in[-R(\alpha+\varepsilon), 0]\right]>1-\varepsilon^{3}
$$

We remark that such paths must be contained in space time rectangle $[-R(\alpha+\varepsilon), R(\alpha+\varepsilon)] \times$ $[0, R]$.
Thus outside probability strictly less than $\frac{1}{\varepsilon} \varepsilon^{3}=\varepsilon^{2}$, we can "navigate" a path $\gamma \in \Gamma^{\frac{R}{\varepsilon}}$ with $S\left(\gamma, \frac{R}{\varepsilon}\right) \leq \frac{1}{\varepsilon} R(\alpha+\varepsilon)$, which lies entirely in spacetime rectangle $[-2 R(\alpha+\varepsilon), 2 R(\alpha+\varepsilon)] \times\left[0, \frac{R}{\varepsilon}\right]$ and which has $\gamma\left(\frac{R}{\varepsilon}\right) \in[-R(\alpha+\varepsilon), R(\alpha+\varepsilon)]$. Therefore we have with probability at least $1-\varepsilon^{2}$ there is a path $\gamma \in \Gamma^{\frac{R}{\varepsilon}}$ so that (i) $S\left(\gamma, \frac{R}{\varepsilon}\right) \leq R(\alpha+\varepsilon)(1+2 \varepsilon) / \varepsilon$
(ii) $\gamma$ lies entirely within $[-2 R(\alpha+\varepsilon), 2 R(\alpha+\varepsilon)] \times\left[0, \frac{R}{\varepsilon}\right]$.

Now provided that $\delta$ is chosen sufficiently small we have also that with probability $>1-\varepsilon^{2}$ we have $\gamma$ satisfying in addition to(i) and (ii) above
(iii) No two jump times of $\gamma$ are within $2 \delta$ of each other or of time 0 or time $\frac{R}{\varepsilon}$. Also the path $\gamma$ is at all times at least $2 \delta$ away from points of $N$ (considered now as a random subset of space time).
We define a 2 -dependent oriented percolation scheme on $\{(m, n): n \geq 0, m+n \equiv 0(\bmod (2))\}$ as follows: We say that the bond from $(m, n)$ to $(m \pm 1, n+1)$ is open if there is a path $\gamma$ from $\left(m R(\alpha+\varepsilon), n \frac{R}{\varepsilon}\right)$ to $\left((m \pm 1) R(\alpha+\varepsilon),(n+1) \frac{R}{\varepsilon}\right)$ that satisfies (i) and
(ii') $\gamma$ lies entirely within $[(m-2) R(\alpha+\varepsilon),(m+2) R(\alpha+\varepsilon)] \times\left[n \frac{R}{\varepsilon},(n+1) \frac{R}{\varepsilon}\right]$.
(iii') No two jump times of $\gamma$ are within $2 \delta$ of each other or of time $n \frac{R}{\varepsilon}$ or time $(n+1) \frac{R}{\varepsilon}$. Also the path $\gamma$ is at all times at least $2 \delta$ away from points of $N$
Then we have that (provided $\varepsilon$ was chosen sufficiently small) the percolation system is supercritical (see the appendix of [D2], which while formally treating oriented bond percolation, is valid for our bond percolation). That is with probability one there is a point $(0, n)$ with infinitely many "descendents".

Lemma 3.1 If $k$ is sufficiently small then for all ( $m, n$ ) if the percolation bond $(m, n) \rightarrow(m \pm 1, n+1)$ is open then with probability at least $k^{\frac{R}{\varepsilon}(\alpha+\varepsilon)(1+3 \varepsilon)}$ a random walk started at $m R(\alpha+\varepsilon)$ at time $n \frac{R}{\varepsilon}$ will survive until time $(n+1) \frac{R}{\varepsilon}$ and will be in position $(m \pm 1) R(\alpha+\varepsilon)$ at this time.

Proof Let a path satisfying (i),(ii') and (iii') be $\gamma$. Let its jumps be at times $0<t_{1}, t_{2}, \cdots t_{r} r \leq$ $R(\alpha+\varepsilon)(1+2 \varepsilon) / \varepsilon$. We consider the event that our random walk makes precisely $r$ jumps in the time interval , these jumps occurring within the intervals $\left(t_{i}-\delta / 3, t_{i}+\delta / 3\right)$ (one jump in each
interval) and the jumps are equal to the corresponding jumps of $\gamma$. This event is contained in the event of interest and has probability at least

$$
e^{-\frac{R}{\varepsilon} k} \prod_{j=1}^{r}\left(\frac{2 \delta}{3} \frac{k}{2}\right)
$$

This is easily seen to exceed $k^{\frac{R}{\varepsilon}(\alpha+\varepsilon)(1+3 \varepsilon)}$ for $k$ small.
Corollary $3.1 \frac{\lambda(k, d)}{\ln \left(\frac{1}{k}\right)} \leq \alpha(d)$.
Proof Given our percolation scheme we have (provided $\varepsilon$ was chosen sufficiently small) that there exists $n_{0}$ so that $\left(0, n_{0}\right)$ is a point of percolation. That is to say there exists $0=m_{0}, m_{1}, \cdots m_{j} \cdots$ so that $\forall j \geq 1$, the bond between $\left(m_{j-1}, n_{0}+j-1\right)$ and $\left(m_{j}, n_{0}+j\right)$ is open.
It follows from induction and Lemma 3.1 that a random walk starting at site 0 at time $n_{0}$ has chance at least $k^{\frac{R}{\varepsilon}(\alpha+\varepsilon)(1+3 \varepsilon) j}$ of surviving until time $\left(n_{0}+j\right) \frac{R}{\varepsilon}$ and being at $m_{j}$ at this time. The chance that a random walk starting at site 0 at time 0 reaches site 0 at time $n_{0} \frac{R}{\varepsilon}$ is strictly positive ( $\underline{N}$ a.s.). So we have for some $c_{k}(\omega)>0$ that

$$
p\left(\left(n_{0}+j\right) \frac{R}{\varepsilon}, N\right) \geq c_{k}(\omega) k^{\frac{R}{\varepsilon}(\alpha+\varepsilon)(1+3 \varepsilon) j}
$$

for $k \leq k_{0}$. Thus $\lambda(k, d) \leq \ln \left(\frac{1}{k}\right)(\alpha+\varepsilon)(1+3 \varepsilon)$. The corollary follows from the arbitrariness of $\varepsilon$.
