## PAPERS COMMUNICATED

## 28．A Problem of Diophantine Approximations in the Old Japanese Mathematics．

By Matsusaburo Fujiwara，m．i．a．<br>Mathematical Institute，Tohoku Imperial University，Sendai． （Comm．April 12，1939．）

In studying the history of the old Japanese mathematics，so－called Wazan，I have found that a manuscript with the title Ruiyaku－zitu （累約術），or the method of successive divisions，written by Katahiro Takebe（建部賢弘，1664－1739），revised in 1728 by his pupil，Genkei Nakane（中根元圭，1662－1733），contains problems of Diophantine approxi－ mations．This manuscript has been mentioned by many mathematicians in our country，but it seems that the importance of its content was not sufficiently perceived by them．

This manuscript consists of the following three problems．The first treats of the integral solutions of $|a x-b y|<1$ ，while the second and the third those of $|a x-b y+c|<1$ and $|a x-b y-c|<1$ respec－ tively，where $a, b, c$ are given positive real numbers．

The author of this manuscript solved the first problem by expand－ ing $b / a$ into simple continued fractions，quite similar to the modern theory of continued fractions．

For the second and the third problems Takebe developed an algorithm very similar to the Jacobi algorithm and gave the concrete form for the solutions，which is very remarkable．

I will translate freely the second problem in the following lines．
Problem．Let $c=5513.9106$ ，the initial additive number（原益數）， be added repeatedly by the successive additive number（累益數）$a=$ 954.5338 and subtracted repeatedly by the successive subtractive num－ ber（累損數）$b=6034.4574$ ．What are the integral values of $x, y$ ，which are called the additive multiplier（益叚數）and the subtractive multi－ plier（損叚數），such that $a x-b y+c$ lies between two given limits（許限） $-\delta$ and $+\delta$ ？［Here it is assumed $b>c, \delta=1$ ］．${ }^{1)}$

The solutions $x, y$ of $0<a x-b y+c<1$ are called the strong ad－ ditive and subtractive multipliers（强益叚，强損叚），while the solutions $x, y$ of $-1<a x-b y+c<0$ the weak additive and subtractive multi－ pliers（弱益叚，弱損叚）．

Answer：the strong additive multiplier 15034， the strong subtractive multiplier 2379 ， the weak additive multiplier 854， the weak subtractive multiplier 136.
Solutions：Since there is the initial additive number $c$ ，we solve this problem by two processes．

The first process runs similarly as the first problem．Divide by $a$ and let the quotient（商）be $a_{1}$ ，the remainder（不盡）be $r_{1}$ ．Next

[^0]divide $a$ by $r_{1}$ and let the quotient be $a_{2}$ ，the remainder $r_{2}$ and so on．
\[

$$
\begin{aligned}
& {\left[\text { Thus } \frac{b}{a}=a_{1}+\frac{r_{1}}{a}, \frac{a}{r_{1}}=a_{2}+\frac{r_{2}}{r_{1}}, \frac{r_{1}}{r_{2}}=a_{3}+\frac{r_{3}}{r_{2}}, \ldots \ldots,\right.} \\
& \text { that is } \left.\frac{b}{a}=a_{1}+\frac{1}{a_{2}}+\frac{1}{a_{3}}+\cdots \cdots .\right] .
\end{aligned}
$$
\]

Let

$$
\begin{array}{lll}
p_{1}=a_{1}, & p_{2}=1+a_{1} a_{2}, \ldots, & p_{n}=a_{n} p_{n-1}+p_{n-2} \\
q_{1}=1, & q_{2}=a_{2}, \ldots \ldots \ldots, & q_{n}=a_{n} q_{n-1}+q_{n-2}
\end{array}
$$

$p_{1}, p_{2}, p_{3}, \ldots$ are called the additive multipliers，while
$q_{1}, q_{2}, q_{3}, \ldots$ the subtractive multipliers．
The second process：$b-c$ is called the initial subtractive number （原損數）．Divide $b-c$ by $a$ and let the quotient be $b_{1}^{\prime}$ ，the remainder $s_{1}^{\prime}$ ；put $b_{1}=b_{1}^{\prime}+1, s_{1}=a-s_{1}^{\prime}$ ．Next divide $s_{1}$ by $r_{1}$ ，and let the quotient be $b_{2}^{\prime}$ ，the remainder $s_{2}^{\prime}$ ；put $b_{2}=b_{2}^{\prime}+1, s_{2}=r_{1}-s_{2}^{\prime}$ ．And so on．
［Thus

$$
\begin{aligned}
& \text { Thus } \quad \frac{b-c}{a}=b_{1}^{\prime}+\frac{s_{1}^{\prime}}{a}=b_{1}-\frac{s_{1}}{a}, \frac{s_{1}}{r_{1}}=b_{2}^{\prime}+\frac{s_{2}^{\prime}}{r_{1}}=b_{2}-\frac{s_{2}}{r_{1}}, \\
& \left.\ldots \ldots \ldots \cdot \frac{s_{n-1}}{r_{n-1}}=b_{n}^{\prime}+\frac{s_{n}^{\prime}}{r_{n-1}}=b_{n}-\frac{s_{n}}{r_{n-1}}\right] .
\end{aligned}
$$

$b_{1}^{\prime}, b_{2}^{\prime}, b_{3}^{\prime}, \ldots$ are called the abundant quotient（盃商），while
$b_{1}, b_{2}, b_{3}, \ldots$ are called the deficient quotient（瞱商），
$s_{1}^{\prime}, s_{2}, s_{3}^{\prime}, s_{4}, s_{5}^{\prime}, \ldots$ are called the weak remainder（弱不盡），
$s_{1}, s_{2}^{\prime}, s_{3}, s_{4}^{\prime}, \ldots$ the strong remainder（强不盡）．
Again let

$$
\begin{array}{lll}
u_{1}^{\prime}=b_{1}^{\prime}, & u_{2}^{\prime}=p_{1} b_{2}^{\prime}+u_{1}, \ldots, & u_{n}^{\prime}=p_{n-1} b_{n}^{\prime}+u_{n-1}, \\
u_{1}=b_{1}, & u_{2}=p_{1} b_{2}+u_{1}, \ldots, & u_{n}=p_{n-1} b_{n}+u_{n-1},
\end{array}
$$

which are called the abundant and the deficient additive multipliers （盈益叚）．Further put

$$
\begin{array}{lll}
v_{1}^{\prime}=1, & v_{2}^{\prime}=q_{1} b_{2}^{\prime}+v_{1}, \ldots, & v_{n}^{\prime}=q_{n-1} b_{n}^{\prime}+v_{n-1}, \\
v_{1}=1, & v_{2}=q_{1} b_{2}+v_{1}, \ldots, & v_{n}=q_{n-1} b_{n}+v_{n-1},
\end{array}
$$

which are called the abundant and the deficient subtractive multipliers （損睹叚）．

The required solutions are to be found among（ $u_{n}, v_{n}$ ）and（ $u_{n}^{\prime}, v_{n}^{\prime}$ ）．

1）In the manuscript the value $c=5513.9116$ is erroneously written 5513.9106 ．
2）To obtain the values $x, y$ as small as possible，it is here given 8 as quotient instead of 11 ．See the remark in the end of this paper．

In the third problem $|a x-b y-c|<1, c$ is taken as the initial subtractive number instead of $b-c$, the remaining part is unchanged.

There is no proof in the manuscript, but perhaps Takebe has obtained these results by inductions. I will verify it in the following lines.

For the sake of simplicity I will change somewhat the notation in the following form.

Let $\alpha, \beta$ be any positive real numbers, and we consider the linear form $x-\alpha y-\beta$, which is the case of the third problem. For the second problem it is considered as $a x-b y+c=a x-b y^{\prime}-c^{\prime}, y^{\prime}=y-1$, $c^{\prime}=b-c$.

$$
\begin{aligned}
& \text { Let } \alpha=a_{1}+\omega_{1}, \quad \frac{1}{\omega_{1}}=a_{2}+\omega_{2}, \ldots, \quad \frac{1}{\omega_{n-1}}=a_{n}+\omega_{n}, \quad\left(0<\omega_{i}<1\right), \\
& \beta=b_{1}-\Omega_{1}, \frac{\Omega_{1}}{\omega_{1}}=b_{2}-\Omega_{2}, \ldots, \quad \frac{\Omega_{n-1}}{\omega_{n-1}}=b_{n}-\Omega_{n}, \quad\left(0<\Omega_{i}<1\right) .
\end{aligned}
$$

If we put $b_{i}^{\prime}=b_{i}-1, \Omega_{i}^{\prime}=1-\Omega_{i}$, then

$$
\beta=b_{1}^{\prime}+\Omega_{1}^{\prime}, \quad \frac{\Omega_{1}}{\omega_{1}}=b_{2}^{\prime}+\Omega_{2}^{\prime}, \ldots \ldots .
$$

Let

$$
\frac{p_{n}}{q_{n}}=a_{1}+\frac{1}{a_{2}}+\frac{1}{a_{3}}+\cdots+\frac{1}{a_{n}},
$$

then it is easily seen that
where

$$
\begin{aligned}
& \alpha=\frac{\omega_{n} p_{n-1}+p_{n}}{\omega_{n} q_{n-1}+q_{n}}, \\
& \beta=\frac{A_{n}+B_{n} \omega_{n}+(-1)^{n} \Omega_{n}}{\omega_{n} q_{n-1}+q_{n}}, \\
& p_{n+1}=a_{n+1} p_{n}+p_{n-1}, \quad q_{n+1}=a_{n+1} q_{n}+q_{n-1}, \\
& A_{n+1}=a_{n+1} A_{n}+B_{n}+(-1)^{n} b_{n+1}, \quad A_{1}=b_{1} \text {, } \\
& B_{n+1}=A_{n}, \quad B_{1}=0 .
\end{aligned}
$$

Putting these values of $\alpha, \beta$ in $x-\alpha y-\beta$, we have

$$
\begin{aligned}
& x-\alpha y-\beta=\left(\omega_{n} q_{n-1}+q_{n}\right)^{-1}\{ x \\
&\left(\omega_{n} q_{n-1}+q_{n}\right)-y\left(\omega_{n} p_{n-1}+p_{n}\right) \\
&\left.-\left(A_{n}+B_{n} \omega_{n}+(-1)^{n} \Omega_{n}\right)\right\}
\end{aligned}
$$

If we define $u_{n}, v_{n}$ by

$$
u_{n} q_{n}-v_{n} p_{n}=A_{n}, \quad u_{n} q_{n-1}-v_{n} p_{n-1}=B_{n},
$$

that is

$$
\begin{aligned}
& u_{n}=(-1)^{n+1}\left(p_{n-1} A_{n}-p_{n} B_{n}\right), \\
& v_{n}=(-1)^{n+1}\left(q_{n-1} A_{n}-q_{n} B_{n}\right),
\end{aligned}
$$

we have

$$
u_{n}-\alpha v_{n}-\beta=(-1)^{n+1} \Omega_{n}\left(\omega_{n} q_{n-1}+q_{n}\right)^{-1} .
$$

From the recurring formula for $A_{n}, B_{n}$, we obtain

$$
u_{n+1}=p_{n} b_{n+1}+u_{n}, \quad v_{n+1}=q_{n} b_{n+1}+v_{n}, \quad u_{1}=b_{1}, \quad v_{1}=1
$$

If we put

$$
\begin{aligned}
u_{n+1}^{\prime} & =p_{n} b_{n+1}^{\prime}+u_{n}, & v_{n+1}^{\prime} & =q_{n} q_{n+1}^{\prime}+v_{n} \\
& =u_{n+1}-p_{n}, & & =v_{n+1}-q_{n}
\end{aligned}
$$

we have

$$
\begin{aligned}
u_{n}^{\prime}-\alpha v_{n}^{\prime}-\beta & =\left(u_{n}-\alpha v_{n}-\beta\right)+\left(\alpha q_{n-1}-p_{n-1}\right) \\
& =\frac{(-1)^{n}\left(1-\Omega_{n}\right)}{\omega_{n} q_{n-1}+q_{n}}
\end{aligned}
$$

since

$$
\alpha q_{n-1}-p_{n-1}=q_{n-1}\left(\frac{\omega_{n} p_{n-1}+p_{n}}{\omega_{n} q_{n-1}+q_{n}}-\frac{p_{n-1}}{q_{n-1}}\right)=\frac{(-1)^{n}}{\omega_{n} q_{n-1}+q_{n}}
$$

Again, if we put $u_{n+1}^{\prime \prime}=p_{n} k_{n+1}+u_{n}, v_{n+1}^{\prime \prime}=q_{n} k_{n+1}+v_{n}$, we have

$$
\begin{aligned}
u_{n}^{\prime \prime}-\alpha v_{n}^{\prime \prime}-\beta & =\left(u_{n-1}-\alpha v_{n-1}-\beta\right)+k_{n+1}\left(p_{n-1}-\alpha q_{n-1}\right) \\
& =\frac{(-1)^{n} \Omega_{n-1}+(-1)^{n-1} k_{n+1}}{\omega_{n-1} q_{n-2}+q_{n-1}}
\end{aligned}
$$

Consequently $\left|u_{n}-\alpha v_{n}-\beta\right|<1 / q_{n},\left|u_{n}^{\prime}-\alpha v_{n}^{\prime}-\beta\right|<1 / q_{n}$; therefore if $1 / q_{m}<\varepsilon$, then $\left(u_{n}, v_{n}\right)\left(u_{n}^{\prime}, v_{n}^{\prime}\right)(n \geqq m)$ are all the solutions of $|x-\alpha y-\beta|<\varepsilon$. Also for sufficiently large $n,\left(u_{n}^{\prime \prime}, v_{n}^{\prime \prime}\right)$ is also a solution of $|x-\alpha y-\beta|<\varepsilon$, if $k_{n+1}<b_{n+1}$. The solutions $\left(u_{n}^{\prime \prime}, v_{n}^{\prime \prime}\right)$ correspond to the intermediary convergents in the theory of continued fractions.

[^0]:    1）［ ］is the remark of the author of this paper．
