(Comm. by Kinjirô KUNUGI, M. J. A., Feb. 12, 1974)

**1. Introduction and Theorem.** Let  $P$  be a  $x_0$ -strictly hyperbolic  $2p \times 2p$ -system of differential operators of first order defined over a  $C^\infty$ -cylinder  $R^1 \times \Omega \subset R^{n+1}$ . Let  $B$  be a  $p \times 2p$ -system of functions defined on the boundary  $\Gamma$  of  $R^1 \times \Omega$ . We consider the following mixed problems under certain conditions:

$$\begin{aligned} P(x, D)u &= f & x \in R^1 \times \Omega & \quad (x_0 > 0), \\ B(x)u &= g & x \in \Gamma & \quad (x_0 > 0), \\ u &= h & \text{on } x_0 = 0 & \end{aligned}$$

where  $\sqrt{-1}D = \left( \frac{\partial}{\partial x_0}, \frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n} \right)$ .

For the sake of simplicity of descriptions, we may only consider the case where  $\Omega = \{x_n > 0\}$ , by the localization process. Then our assumptions are the following:

(I)  $\alpha$ ) The coefficients of  $P$  and  $B$  are real, belong to  $C^\infty(R^1 \times \bar{\Omega})$  and constant outside some compact set of  $R^1 \times \bar{\Omega}$ .

$\beta$ ) For  $P$ , it satisfies the  $\#$  condition with respect to  $\Gamma$  and for fixed real  $(x, \tau, \sigma)$  there is at most one real double root  $\lambda$  of  $|P|(x, \tau, \sigma, \lambda) = 0$  where  $x \in \Gamma$ . Furthermore it is non-characteristic with respect to  $\Gamma$  and it is normal, i.e.

$$|P|(x, 0, \sigma, \lambda) \neq 0$$

for any real  $(\sigma, \lambda) \neq 0$ .

$\gamma$ ) The  $p$  row-vectors of  $B(x)$  are linearly independent, where  $x \in \Gamma$ .

(II)  $\alpha$ ) If the Lopatinsky determinant  $R(x_0, \tau_0, \sigma_0) = 0$  for a real point  $(x_0, \tau_0, \sigma_0)$  such that there are no real double roots  $\lambda$  of  $|P|(x_0, \tau_0, \sigma_0, \lambda) = 0$ , then

$$|R(x_0, \tau_0 - i\gamma, \sigma_0)| \geq 0(\gamma^1) \quad (\gamma > 0).$$

Furthermore if there is at least one real simple root  $\lambda(x_0, \tau_0, \sigma_0)$ , the zero set of  $R(x, \tau \pm i\gamma, \sigma)$  in some neighborhood  $U(x_0, \tau_0, \sigma_0)$  is in the set  $\{\gamma = 0\}$ .

$\beta$ ) If  $R(x_0, \tau_0, \sigma_0) = 0$  for a real point  $(x_0, \tau_0, \sigma_0)$  such that there are real double roots  $\lambda$  of  $|P|(x_0, \tau_0, \sigma_0, \lambda) = 0$ , then

$$|R(x_0, \tau_0 - i\gamma, \sigma_0)| \geq 0(\gamma^{1/2}) \quad (\gamma > 0).$$

Furthermore if there is at least one real simple root  $\lambda$ , the rank of the

Hessian of  $R(x, \tau, \sigma)$  at its zeros in some  $U(x_0, \tau_0, \sigma_0)$  is equal to  
 codim. of  $\{R(x, \tau, \sigma)=0\}$  in  $R^{2n-1}$ .

Where the zero set of  $R(x, \tau, \sigma)$  in some  $U(x_0, \tau_0, \sigma_0)$  is preassumed to be a regular submanifold of  $R^{2n}$ .

$\gamma$ ) Moreover, if there is at least one non-real root  $\lambda$  of  $|P|(x_0, \tau_0, \sigma_0, \lambda)=0$  for the point  $(x_0, \tau_0, \sigma_0)$  which satisfies the condition  $\beta$ ), then for some smooth and non-singular matrix  $S(x, \tau - i\gamma, \sigma)$  with  $\gamma \geq 0$  defined on some  $U(x_0, \tau_0, \sigma_0)$ , one of the corresponding coupling coefficients  $b_{\text{III}}(x, \tau, \sigma)$  is real whenever  $\tau$  and  $\lambda_{\text{II}}^+(x, \tau, \sigma)$  are real (For definitions, see § 2).

(III) Any constant coefficients problems frozen the coefficient at boundary are  $L^2$ -well posed.

Then we have the following

**Theorem.** *Under assumptions (I), (II), (III), the mixed problem is  $L^2$ -well posed.*

The aim of the present note is to describe the outline of our proof of the above assertion. Here we use essentially the conception of reflection coefficients ([1], [2]) and modifying Kreiss' consideration ([4]) we make use of the micro-localization of the characterization for  $L^2$ -well posed mixed problem of order two ([1], [3] and [7]).

**2. The outline of the proof.** Considering the assumption (I) let  $S(x, \tau - i\gamma, \sigma)$  ( $\gamma \geq 0$ ) be a smooth, non-singular matrix defined on some neighborhood  $U(x_0, \tau_0, \sigma_0)$  such that

$$S^{-1}PS = ED_n - A(x, \tau - i\gamma, \sigma)$$

where

$$A = \begin{bmatrix} \lambda_{\text{I}}^+ & & & & \\ & \lambda_{\text{I}}^- & & & \\ & & A_{\text{II}} & & \\ & & & A_{\text{III}}^+ & \\ & & & & A_{\text{III}}^- \end{bmatrix},$$

$$\lambda_{\text{I}}^\pm = \begin{bmatrix} \cdot & & & & \\ & \cdot & & & \\ & & \lambda_i^\pm & & \\ & & & \cdot & \\ & & & & \cdot \end{bmatrix}, \quad i \in \text{I}, \quad |\text{I}| = r,$$

$\lambda_i^\pm$  are real for  $\gamma=0$ , and  $\text{Im } \lambda_i^+ (\text{Im } \lambda_i^-) > 0 (< 0)$  respectively if  $\gamma > 0$ .  
 Next for  $\tau_0 = \tau_0(x, \sigma)$

$$A_{\text{II}}(x, \tau_0, \sigma) = \begin{pmatrix} a(x, 0, \sigma) & 1 \\ 0 & a(x, 0, \sigma) \end{pmatrix}.$$

Here we may restrict ourself to the case where the eigenvalue of  $A_{\text{II}}(x, \tau, \sigma)$  are described by the following form in some  $U(x_0, \tau_0, \sigma_0)$ ;

$$\lambda_{\text{II}}^\pm = a(x, \zeta, \sigma) \mp \sqrt{\zeta} b(x, \zeta, \sigma) \quad (\sqrt{1} = 1),$$

$a(x, \zeta, \sigma)$ ,  $b(x, \zeta, \sigma)$  are real when  $\zeta$  is real,  $b(x, \zeta, \sigma) \neq 0$ ,  $\tau_0 = \tau_0(x_0, \sigma_0)$ ,

$\tau = \zeta + \tau_0(x, \sigma)$  and  $\tau_0(x, \sigma)$  is real and positive.

Furthermore  $A_{\text{III}}^\pm$  have only non-real eigenvalues for any  $\gamma \geq 0$  and the ones of  $A_{\text{III}}^+$  have positive imaginary parts.

Let  $BS = (V_I^+, V_I^-, V_{\text{II}}^+, V_{\text{II}}'', V_{\text{III}}^+, V_{\text{III}}^-)$ . Where  $V_I^\pm$  are  $(p \times r)$ -matrices,  $V_{\text{II}}^+, V_{\text{II}}''$  are  $p$ -vectors and  $V_{\text{III}}^\pm$  are  $(p \times s)$ -matrices respectively  $(2r + 2 + 2s = 2p)$ .

$$\text{Let } S_{\text{II}} = \begin{pmatrix} 1 & 0 \\ \frac{\lambda_{\text{II}}^+ - h_{11}\zeta - a}{1 + h_{12}\zeta} & 1 \end{pmatrix}, \quad a = a(x, 0, \sigma)$$

and let

$$S' = \begin{pmatrix} E_{2r} & & \\ & S_{\text{II}} & \\ & & E_{2s} \end{pmatrix},$$

where  $h_{ij}$  are the functions derived from  $A_{\text{II}}(x, \tau - i\gamma, \sigma)$ . Furthermore we denote  $B \cdot S \cdot S'$  by

$$(V_I^+, V_I^-, V_{\text{II}}^+, V_{\text{II}}^-, V_{\text{III}}^+, V_{\text{III}}^-)(x, \tau, \sigma).$$

Then from our assumptions we obtain the following Lemmas. In particular from (I)  $\gamma$ ), (II)  $\alpha$ ) and (III), we see the following

**Lemma 2.1.** *If for real  $(x_0, \tau_0, \sigma_0)$  there exist no real double roots  $\lambda$ , then there is neighborhood  $U(x_0, \tau_0, \sigma_0)$  where*

i) *For some  $V_{3,i}^-$  the determinant*

$$|V_I^+, V_{3,1}^+, \dots, V_{3,i-1}^+, V_{3,i}^-, V_{3,i+1}^+, \dots, V_{3,s}^+| \neq 0$$

where  $V_{\text{III}}^+ = (V_{3,1}^+, \dots, V_{3,s}^+)$ ,  $s = p - \gamma$ ,  $V_{3,i}^+$  are  $p$ -column vectors (Here after let  $i = 1$ ).

ii) *For some  $V_{3,1}^+$  it belongs to the linear subspace  $L(V_{3,2}^+, \dots, V_{3,s}^+)$  spanned by the vectors  $V_{3,2}^+, \dots, V_{3,s}^+$ .*

iii) *The column vectors of  $V_I^-$  belong to  $L(V_I^+, V_{3,2}^+, \dots, V_{3,s}^+)$ . But ii) and iii) are only valid at the points  $\in U(x_0, \tau_0, \sigma_0)$  such that the Lopatinsky  $\det. |V_I^+, V_{\text{III}}^+|(x, \tau, \sigma) = c(\tau - \tau(x, \sigma)) = 0$  ( $c \neq 0$ ) and where  $\tau(x, \sigma)$  is real whenever  $V_I^+$  present.*

From (II)  $\beta$ ) and  $\gamma$ ) we see the following

**Lemma 2.2.** *Let  $(x_0, \tau_0, \sigma_0)$  be a real point such that there exists a real double root  $\lambda$ . Let  $|V_I^+, V_{\text{II}}^+, V_{\text{III}}^+|(x_0, \zeta, \sigma_0) = 0$ , where we consider  $\zeta$  as a new variable instead of  $\tau$ . Then*

i)  $\zeta = 0$ .

ii) *Let  $\zeta^{1/2} = \eta$ , then*

$$|V_I^+, V_{\text{II}}^+, V_{\text{III}}^+| = C(\eta - \eta(x, \sigma)) \quad (c \neq 0)$$

in some  $U(x_0, \tau_0, \sigma_0)$ , where  $\eta(x, \sigma)$  may take complex values.

Under the assumption of Lemma 2.2 we see the following Lemmas.

**Lemma 2.3.** i) *The coupling coefficient*

$$\begin{aligned} b_{\text{IIII}}(x_0, -i\gamma, \sigma_0) &= \frac{|V_I^+, V_{\text{II}}^-, V_{\text{III}}^+|}{|V_I^+, V_{\text{II}}^+, V_{\text{III}}^+|}(x_0, -i\gamma, \sigma_0) \\ &= 0(\gamma^{-1/2}) \quad (\gamma > 0). \end{aligned}$$

ii) Let  $Q(x, \zeta, \sigma)$  be  $\frac{a_{11} + a_{21}b_{II\ II}}{a_{12} + a_{22}b_{II\ II}}$ , then it is  $\frac{|V_I^+, V_{II}^+, V_{III}^+|}{|V_I^+, V_{II}^+, V_{III}^+|}$ , where

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} = S_{II}^{-1}.$$

Now from Lemma 2.3 and (III) we obtain the following

**Lemma 2.4.**

- i)  $|V_I^+, V_{II}^+, V_{III}^+| \neq 0$ .
- ii)  $V_{II}^+ \in L(V_{III}^+)$  on  $\zeta = \eta(x, \sigma) = 0$ .
- iii)  $V_I^- \in L(V_I^+, V_{III}^+)$  on  $\zeta = \eta(x, \sigma) = 0$ .
- iv)  $V_{II}'' - QV_{II}'' \in L(V_I^+, V_{III}^+)$ .

From (II)  $\beta$ ,  $\gamma$ ), (III) and the definition of  $Q$  we see the following

**Lemma 2.5.** i) *The above defined  $Q(x, \zeta, \sigma)$  takes only real values, when  $\zeta$  is real.*

- ii)  $\zeta = 0, Q(x, 0, \sigma) = 0$  are equivalent to  $R(x, \zeta, \sigma) = 0$  for  $\text{Im } \zeta \leq 0$ .
- iii)  $-Q(x, 0, \sigma) \geq 0$ .

From Lemma 2.4 we obtain the following

**Lemma 2.6.** *For  $(x, \zeta, \sigma)$  belonging to some  $U(x_0, \tau_0, \sigma_0)$ ,*

$$g = (V_I^+, V_{II}^+, V_{III}^+) \begin{pmatrix} U_I^+ + (\zeta K'_{II\ II} + K''_{II\ II})U' + K_{II}U_I^- \\ U_{II}'' + QU_{II}'' + (\zeta K'_{II\ I} + K''_{II\ I})U_I^- \\ U_{III}^+ + K_{III\ I}U_I^- + K_{III\ II}U_{II}'' \end{pmatrix} + V_{III}^- U_{III}^-$$

where  $u = (U_I^+, U_I^-, U_{II}^+, U_{II}'', U_{III}^+, U_{III}^-)$ . Moreover the components of  $K''_{II\ II}$  and  $K''_{II\ I}$  are zero, whenever  $\zeta = 0$  and  $\eta(x, \sigma) = 0$ .

From Lemma 2.1 we obtain an a priori  $L^2$ -estimate in the case where there is no real double root  $\lambda$ . On the other hand if there is at least one real double root  $\lambda$ , we see from Lemma 2.5 and by some modifications of Kreiss' method that the problem  $((D_n - A_{II})u = f, u'' + Qu' = g)$  has a priori estimate

$$\|(D_n - A_{II})u\|_{0,r} + \langle\langle g \rangle\rangle_{1/2,r} \geq C\gamma \|u\|_{0,r} \quad (C > 0)$$

where  $\text{supp } u \subset U(x_0)$ , spectrum of  $u$  with respect to  $x_0, \dots, x_{n-1} \subset U(\tau_0, \sigma_0)$ . Then from the method of the proof of the above estimate and from Lemma 2.6, we obtain a similar estimate in this case. Here we use the fact that the components  $k$  of  $K'_{II\ II}, K''_{II\ II}$  has the following form: in some  $U(x_0, \tau_0, \sigma_0)$

$$k(x, \zeta, \sigma) = \tilde{k}(x, 0, \sigma) + \zeta \tilde{\tilde{k}}(x, 0, \sigma) + 0(|\zeta|^2), \\ |\tilde{k}(x, 0, \sigma)|^2 \leq K |Q(x, 0, \sigma)| \quad (K > 0)$$

which follows from the last assumption of (II),  $\beta$ ).

Furthermore our assumptions are valid for the dual problem and hence a priori estimate for that problem is also obtained. Thus our proof is complete ([6]).

**Remark.** The conditions (I), (II), (III) are invariant for certain coordinate transformations. Hence Theorem is applicable for problems defined on any smooth  $R^1 \times \Omega$ .
