# 11. On a Problem of Yamamoto Concerning Biquadratic Gauss Sums 

By Hiroshi Ito<br>Department of Mathematics, Faculty of Science, Nagoya University<br>(Communicated by Shokichi Iyanaga, m. J. A., Feb. 12, 1987)

Yamamoto [4] observed some relations, which can be stated as (I)~(IV) below, between the biquadratic Gauss sums and the generalized Bernoulli numbers defined for prime numbers $p<4,000$ such that $p \equiv 1(\bmod 4)$. He proposed the question whether these relations were always true. In this note, we report counter-examples to (I) $\sim$ (III) and prove (IV). Some remarks on a problem which still remains will be added.

1. For a prime number $p \equiv 1(\bmod 4)$, take positive integers $a$ and $b$ such that $p=a^{2}+4 b^{2}$ and put $\omega=\omega_{p}:=a+2 b i$. Define the Dirichlet character $\chi=\chi_{p}$ modulo $p$ by $\chi(m)=(m / \omega)_{4}$ where $(m / \omega)_{4}$ is the biquadratic residue symbol in $\boldsymbol{Q}(i)$, the Gauss' number field. Consider the Gauss sum

$$
\tau(\chi)=\sum_{m=1}^{p-1} \chi(m) e^{2 \pi i m / p}
$$

We write

$$
\tau(\chi)=\varepsilon_{p} \omega^{1 / 2} p^{1 / 4} \quad \text { with } \quad 0<\arg \left(\omega^{1 / 2}\right)<\pi / 4
$$

It is a classical result that $\varepsilon_{p}^{4}=1$. On the other hand we put

$$
A_{p}=-\frac{1}{p} \sum_{m=1}^{p-1} \chi(m) m, \quad B_{p}=-\frac{1}{p} \sum_{m=1}^{(p-1) / 2} \chi(m) m, \quad C_{p}=\sum_{m=1}^{(p-1) / 2} \chi(m)
$$

Then the assertions (I) $\sim(I V)$ in [4] (p. 212) can be stated as follows:
(IV)

$$
\begin{array}{ll}
-\pi / 4 \leq \arg \left(\varepsilon_{p} \bar{A}_{p}\right)<3 \pi / 4 & \text { if } p \equiv 5(\bmod 8), \\
-\pi \leq \arg \left(\varepsilon_{p} \bar{B}_{p}\right)<0 & \text { if } p \equiv 5(\bmod 8), \\
\operatorname{Im}\left(\varepsilon_{p} \bar{C}_{p}\right)>0 & \text { if } p \equiv 5(\bmod 8),  \tag{III}\\
\operatorname{Re}\left(\varepsilon_{p} \bar{B}_{p}\right)>0 & \text { if } p \equiv 1(\bmod 8),
\end{array}
$$

where the bar indicates the complex conjugation. Note that $A_{p}=C_{p}=0$ if $p \equiv 1(\bmod 8)$, when the character $\chi$ satisfies $\chi(-1)=1$.

At the time when [4] was published, the calculation of $\varepsilon_{p}$ was very hard. Now we have an elegant expression of $\varepsilon_{p}$ obtained by Matthews [3]. Define $\delta_{p} \in\{1,-1\}$ by

$$
\{(p-1) / 2\}!\equiv \delta_{p} i(\bmod \omega)
$$

Then it follows from [3] that

$$
\varepsilon_{p}=-\delta_{p} \chi(2 i)\left(\frac{b}{a}\right)_{2} \times \begin{cases}i & \text { if } a \equiv 1(\bmod 4), \\ 1 & \text { if } a \equiv 3(\bmod 4),\end{cases}
$$

where $(b / a)_{2}$ is the (rational) Jacobi symbol. By means of this expression for $\varepsilon_{p}$, the author examined, with the help of an electronic computer, the assertions (I) $\sim$ (III) for $p<1,000,000$ and found counter-examples. There
are 19,623 prime numbers congruent to 5 modulo 8 up to $1,000,000$ and the numbers of counter-examples for (I), (II) and (III) are 282, 106 and 1 respectively. The smallest counter-examples are as follows :
( I ) $\quad p=3821, \quad A_{p}=-17+21 i, \quad \varepsilon_{p}=-i$,
(II ) $\quad p=5477, \quad B_{p}=1-14 i, \quad \varepsilon_{p}=i$,
(III) $\quad p=440093, \quad C_{p}=355+35 i, \quad \varepsilon_{p}=1$.

The assertion (IV) is true. We will give a proof of it in the next paragraph. (Although Yamamoto [4] says that (I)~(IV) were verified up to 4,000, we have found the above counter-example to (I) lying in this range.)
2. As is well-known the values at positive integers of the $L$-series

$$
L(s, \chi)=\sum_{n=1}^{\infty} \chi(n) n^{-s} \quad(\operatorname{Re}(s)>1)
$$

are expressed in terms of the Gauss sum $\tau(\chi)$ and the generalized Bernoulli numbers, and all the assertions from (I) to (IV) can be translated into assertions about $\arg (L(1, \chi))$ or $\arg (L(2, \chi))$. (Concerning this point the author has benefited from a remark made by Heath-Brown and Patterson in Berndt and Evans [1].) This translation gives a proof of (IV) and a viewpoint for understanding the computational result that the numbers of counter-examples for (I) $\sim$ (III) are small.

If we note the relations

$$
B_{p}=-\frac{1}{2}(1+\chi(2)) A_{p}, \quad C_{p}=2\left(1-\frac{\overline{\chi(2)}}{2}\right) A_{p} \quad \text { if } p \equiv 5(\bmod 8)
$$

and

$$
B_{p}=p^{-2}\left(1-\frac{\overline{\chi(2)}}{4}\right) \sum_{m=1}^{p-1} \chi(m) m^{2} \quad \text { if } p \equiv 1(\bmod 8)
$$

it is immediately seen that the assertions from (I) to (IV) are equivalent to the following assertions from ( $\mathrm{I}^{\prime}$ ) to ( $\mathrm{IV}^{\prime}$ ) respectively :

| ( $\mathrm{I}^{\prime}$ ) | $-3 \pi / 4 \leq \arg \left(L\left(1, \chi_{p}\right) / \omega_{p}^{1 / 2}\right)<\pi / 4$ | if $p \equiv 5(\bmod 8)$, |
| :--- | :--- | :--- |
| (II' $)$ | $-\pi / 2 \leq \arg \left(\left(1-\chi_{p}(2)\right) L\left(1, \chi_{p}\right) / \omega_{p}^{1 / 2}\right)<\pi / 2$ | if $p \equiv 5(\bmod 8)$, |
| (III' $\left.^{\prime}\right)$ | $\operatorname{Re}\left(L\left(1, \chi_{p}^{\prime}\right) / \omega_{p}^{1 / 2}\right)>0$ | if $p \equiv 5(\bmod 8)$, |
| (IV') | $\operatorname{Re}\left(L\left(2, \chi_{p}^{\prime}\right) / \omega_{p}^{1 / 2}\right)>0$ | if $p \equiv 1(\bmod 8)$, |

where $\chi_{p}^{\prime}$ is the Dirichlet character modulo $2 p$ induced from $\chi_{p}$. Easy calculation using the Euler product for $L\left(2, \chi_{p}^{\prime}\right)$ shows

$$
-\pi / 4<\arg \left(L\left(2, \chi_{p}^{\prime}\right)\right)<\pi / 4
$$

and this proves (IV') and (IV).
The author calculated, by an electronic computer, $\arg \left(L\left(1, \chi_{p}^{\prime}\right)\right)$ for prime numbers $p<1,000,000$ such that $p \equiv 5(\bmod 8)$. The calculation shows that $\arg \left(L\left(1, \chi_{p}^{\prime}\right)\right)$, considered as an element of $R / 2 \pi Z$, tends to be close to zero (see Table I). This tendency is clearly related to the tendency of the inequalities in (I) $\sim$ (III), or equivalently in $\left(\mathrm{I}^{\prime}\right) \sim\left(\mathrm{III}^{\prime}\right)$, to be satisfied. Precise formulation of the distribution of $\arg \left(L\left(1, \chi_{p}^{\prime}\right)\right)$ will be possible by the method developed in Elliott [2].

## Table I

The numbers $F(n)$ of primes $p$ such that $p \equiv 5(\bmod 8), p<1,000,000$ and $(n-1) \pi / 100 \leq \arg \left(L\left(1, \chi_{p}^{\prime}\right)\right)<n \pi / 100$ are listed. We have $F(n)=0$ for $35 \leq n \leq 169$.

| $n$ | $F(n)$ | $n$ | $F(n)$ |
| :---: | :---: | :---: | :---: |
| 1 | 682 | 200 | 773 |
| 2 | 770 | 199 | 748 |
| 3 | 725 | 198 | 755 |
| 4 | 699 | 197 | 713 |
| 5 | 659 | 196 | 738 |
| 6 | 672 | 195 | 700 |
| 7 | 661 | 194 | 596 |
| 8 | 593 | 193 | 596 |
| 9 | 557 | 192 | 526 |
| 10 | 480 | 191 | 488 |
| 11 | 454 | 190 | 455 |
| 12 | 440 | 189 | 411 |
| 13 | 405 | 188 | 378 |
| 14 | 327 | 187 | 362 |
| 15 | 317 | 186 | 288 |
| 16 | 255 | 185 | 238 |
| 17 | 251 | 184 | 209 |
| 18 | 174 | 183 | 170 |
| 19 | 152 | 182 | 168 |
| 20 | 134 | 181 | 136 |
| 21 | 101 | 180 | 111 |
| 22 | 83 | 179 | 92 |
